☒ This report is available. *Complete sections 2a - 2f.*

☐ This report is not available. *Complete section 3.*

2a. Number of Copies Forwarded: 1 each

2b. Forwarding Date: July/2000

2c. Distribution Statement *(Please check ONE box)*

DoD Directive 5230.24, "Distribution Statements on Technical Documents," 18 Mar 87, contains seven distribution statements, as described briefly below. Technical documents MUST be assigned a distribution statement.

☒ DISTRIBUTION STATEMENT A: Approved for public release. Distribution is unlimited.

☐ DISTRIBUTION STATEMENT B: Distribution authorized to U.S. Government Agencies only.

☐ DISTRIBUTION STATEMENT C: Distribution authorized to U.S. Government Agencies and their contractors.

☐ DISTRIBUTION STATEMENT D: Distribution authorized to U.S. Department of Defense (DoD) and U.S DoD contractors only.

☐ DISTRIBUTION STATEMENT E: Distribution authorized to U.S. Department of Defense (DoD) components only.

☐ DISTRIBUTION STATEMENT F: Further dissemination only as directed by the controlling DoD office indicated below or by higher authority.

☐ DISTRIBUTION STATEMENT X: Distribution authorized to U.S. Government agencies and private individuals or enterprises eligible to obtain export-controlled technical data in accordance with DoD Directive 5230.25, Withholding of Unclassified Technical Data from Public Disclosure, 6 Nov 84.

2d. Reason For the Above Distribution Statement *(in accordance with DoD Directive 5230.24)*

2e. Controlling Office: HQ AFCEE

2f. Date of Distribution Statement Determination: 15 Nov 2000

3. This report is NOT forwarded for the following reasons. *(Please check appropriate box)*

☐ It was previously forwarded to DTIC on _____ *(date)* and the AD number is _____

☐ It will be published at a later date. Enter approximate date if known. _____

EXECUTIVE SUMMARY

This report summarizes the field activities conducted at Havre AFS, for a short-term field pilot test to compare vacuum-enhanced free-product recovery (bioslurping) to traditional free-product recovery techniques to remove light, nonaqueous-phase liquid (LNAPL) from subsurface soils and aquifers. The field testing at Havre AFS is part of the Bioslurper Initiative, which is funded and managed by the U.S. Air Force Center for Environmental Excellence (AFCEE) Technology Transfer Division. The AFCEE Bioslurper Initiative is a multisite program designed to evaluate the efficacy of the bioslurping technology for (1) recovery of LNAPL from groundwater and the capillary fringe, and (2) enhancing natural in situ degradation of petroleum contaminants in the vadose zone via bioventing.

The main objective of the Bioslurper Initiative is to develop procedures for evaluating the potential for recovering free-phase LNAPL present at petroleum-contaminated sites. The overall study is designed to evaluate bioslurping and identify site parameters that are reliable predictors of bioslurping performance. To measure LNAPL recovery in a wide variety of in situ conditions, tests are being performed at many sites. The tests at Havre AFS are two of over 40 similar field tests to be conducted at various locations throughout the United States and its possessions.

The intent of field testing is to collect data to support determination of the predictability of LNAPL recovery and to evaluate the applicability, cost, and performance of the bioslurping technology for removal of free product and remediation of the contaminated area. The on-site testing is structured to allow direct comparison of the LNAPL recovery achieved by bioslurping with the performance of more conventional LNAPL recovery technologies. The test method included an initial site characterization followed by LNAPL recovery testing. The three LNAPL recovery technologies tested at Havre AFS were skimmer pumping, bioslurping, and drawdown pumping.

Bioslurper pilot test activities were conducted at two spill sites located within the same general area of the Base Housing Area. Minimal site characterization activities were carried out at Site 1 (monitoring well MW-F), since little free product was recovered at this site. The full scope of Bioslurper Initiative testing was conducted at Site 2 (monitoring well MW-7).

Site characterization activities were conducted to evaluate site variables that could affect LNAPL recovery efficiency and to determine the bioventing potential of the site. Testing included baildown testing to evaluate the mobility of LNAPL, soil sampling to determine physical/chemical site characteristics, soil gas permeability testing to determine the radius of influence, and in situ respiration testing to evaluate site microbial activity.

Following the site characterization activities, the pump tests were conducted. At Site 1, a 45-hour bioslurper pump test was conducted at monitoring well MW-F. At Site 2, pilot tests for skimmer pumping, bioslurping, and drawdown pumping were conducted at monitoring well MW-7. The LNAPL recovery testing was conducted in the following sequence at monitoring well MW-7: 39 hours in the skimmer configuration, approximately 98 hours in the bioslurper configuration, 47 hours in the drawdown configuration, and an additional 27 hours in the skimmer configuration. Measurements of extracted soil gas composition, LNAPL thickness, and groundwater level were taken throughout the testing. The volume of LNAPL recovered and groundwater extracted were quantified over time.

None of the LNAPL recovery techniques were successful at recovering free product. These results indicate that there is little free product present at the two sites or that it is relatively immobile. As a result, it was decided to install a bioventing system at both sites to remediate the vadose zone. Bioventing systems were configured to inject air into monitoring well MW-F at Site 1 and monitoring well MW-7 at Site 2.

Soil gas concentrations were measured at monitoring points during the bioslurper pump test to determine whether the vadose zone was being oxygenated. At Site 1, oxygen concentrations increased only at the closest monitoring point; however, based on radius of influence testing, it is likely that soil gas at greater distances will become oxygenated over time. At Site 2, all monitoring points exhibited increased oxygen concentrations. These results correlated with results from the soil gas permeability test where a radius of influence of approximately 12 ft was determined. The radius of influence of the bioventing system potentially may be greater than 12 ft, since the system is configured for air injection. With the radius of influence from these systems, bioventing is treating the entire contaminant plume at both sites.

Implementation of bioslurping or any free-product recovery technique at the Havre AFS test site does not appear likely to facilitate enhanced recovery of LNAPL from the water table and simultaneous in situ biodegradation of hydrocarbons in the vadose zone via bioventing. A large volume of free product does not appear to be present; therefore, bioventing is recommended to remediate vadose zone contamination.

FINAL SITE-SPECIFIC TECHNICAL REPORT (A003)

for

FREE PRODUCT RECOVERY TESTING AT THE BASE HOUSING AREA, HAVRE AFS, MONTANA

20 February 1997

1.0 INTRODUCTION

This report describes activities performed and data collected during field tests at Havre Air Force Station (AFS), Montana, to compare vacuum-enhanced free-product recovery (bioslurping) to traditional free-product recovery technologies for removal of light, nonaqueous-phase liquid (LNAPL) from subsurface soils and aquifers. The field testing at Havre AFS is part of the Bioslurper Initiative, which is funded and managed by the U.S. Air Force Center for Environmental Excellence (AFCEE) Technology Transfer Division. The AFCEE Bioslurper Initiative is a multisite program designed to evaluate the efficacy of the bioslurping technology for (1) recovery of LNAPL from groundwater and the capillary fringe and (2) enhancing natural in situ degradation of petroleum contaminants in the vadose zone via bioventing.

1.1 Objectives

The main objective of the Bioslurper Initiative is to develop procedures for evaluating the potential for recovering free-phase LNAPL present at petroleum-contaminated sites. The overall study is designed to evaluate bioslurping and identify site parameters that are reliable predictors of bioslurping performance. To measure LNAPL recovery in a wide variety of in situ conditions, tests are being performed at many sites. The tests at Havre AFS are two of over 40 similar field tests to be conducted at various locations throughout the United States and its possessions. Aspects of the testing program that apply to all sites are described in the *Test Plan and Technical Protocol for Bioslurping* (Battelle, 1995). Test provisions specific to activities at Havre AFS were described in the Site-Specific Test Plan provided in Appendix A.

The intent of field testing is to collect data to support determination of the predictability of LNAPL recovery and to evaluate the applicability, cost, and performance of the bioslurping

technology for removal of free product and remediation of the contaminated area. The on-site testing is structured to allow direct comparison of the LNAPL recovery achieved by bioslurping with the performance of more conventional LNAPL recovery technologies. The test method included an initial site characterization followed by LNAPL recovery testing. The three LNAPL recovery technologies tested at Havre AFS were skimmer pumping, bioslurping, and drawdown pumping. The specific test objectives, methods, and results for the Havre AFS test program are discussed in the following sections.

1.2 Testing Approach

Bioslurper pilot test activities were conducted at two spill sites located within the same general area of the Base Housing Area. Minimal site characterization activities were carried out at Site 1 (monitoring well MW-F), since little free product was recovered at this site. The full scope of Bioslurper Initiative testing was conducted at Site 2 (monitoring well MW-7). Results from the two test sites are presented separately in the following sections.

Site characterization activities were conducted to evaluate site variables that could affect LNAPL recovery efficiency and to determine the bioventing potential of the site. Testing included baildown testing to evaluate the mobility of LNAPL, soil sampling to determine physical/chemical site characteristics, soil gas permeability testing to determine the radius of influence, and in situ respiration testing to evaluate site microbial activity.

Following the site characterization activities, the pump tests were conducted. At Site 1, a 45-hour bioslurper pump test was conducted at monitoring well MW-F. At Site 2, pilot tests for skimmer pumping, bioslurping, and drawdown pumping were conducted at monitoring well MW-7. The LNAPL recovery testing was conducted in the following sequence at monitoring well MW-7: 39 hours in the skimmer configuration, approximately 98 hours in the bioslurper configuration, 47 hours in the drawdown configuration, and an additional 27 hours in the skimmer configuration. Measurements of extracted soil gas composition, LNAPL thickness, and groundwater level were taken throughout the testing. The volume of LNAPL recovered and groundwater extracted were quantified over time.

2.0 SITE DESCRIPTION

The Base Housing Area contains many underground storage tanks (USTs) that were installed in the 1950's. The USTs were used to store heating oil and diesel fuel. In 1984, the Investigative Restoration Program was employed at Havre AFS to determine releases of heating oil and diesel fuel that may pose a threat to human health and the environment in the area. It was found that 19 out of 26 USTs in the Base Housing Area had leaked fuel oil into the surrounding soils. The USTs were removed in September 1992.

Havre AFS geologic conditions are characterized by approximately 15 ft of soil and unconsolidated material which is underlain by the Upper Cretaceous Bearpaw Shale. The unconsolidated materials are mostly comprised of fine sandy loam and clay loam. These loams are generally derived from parent materials of glacial till and tend to form deep soil horizons. Depth to groundwater varies from 10 to 17 ft below ground surface. Groundwater generally occurs in sand lenses lying atop the sandy and clay loams.

Soil samples collected during the UST removal indicated levels of TPH (as diesel) to be 35,200 mg/kg at a depth of 1 ft in the vicinity of monitoring well MW-F. Monitoring wells MW-7 and MW-F have shown measurable free product thickness. Figure 1 is a schematic diagram of the housing facilities and monitoring wells located in the Base Housing Area.

3.0 BIOSLURPER SHORT-TERM PILOT TEST METHODS

This section documents the initial conditions at the test site and describes the test equipment and methods used for the short-term pilot test at Havre AFS.

3.1 Site 1: Activities at Monitoring Well MW-F

3.1.1 Initial LNAPL/Groundwater Measurements and Baildown Testing

Monitoring well MW-F was evaluated for use in the bioslurper pilot testing. Initial depths to LNAPL and to groundwater were measured using an oil/water interface probe (ORS Model #1068013). LNAPL was removed from the well with a Teflon™ bailer until the LNAPL thickness

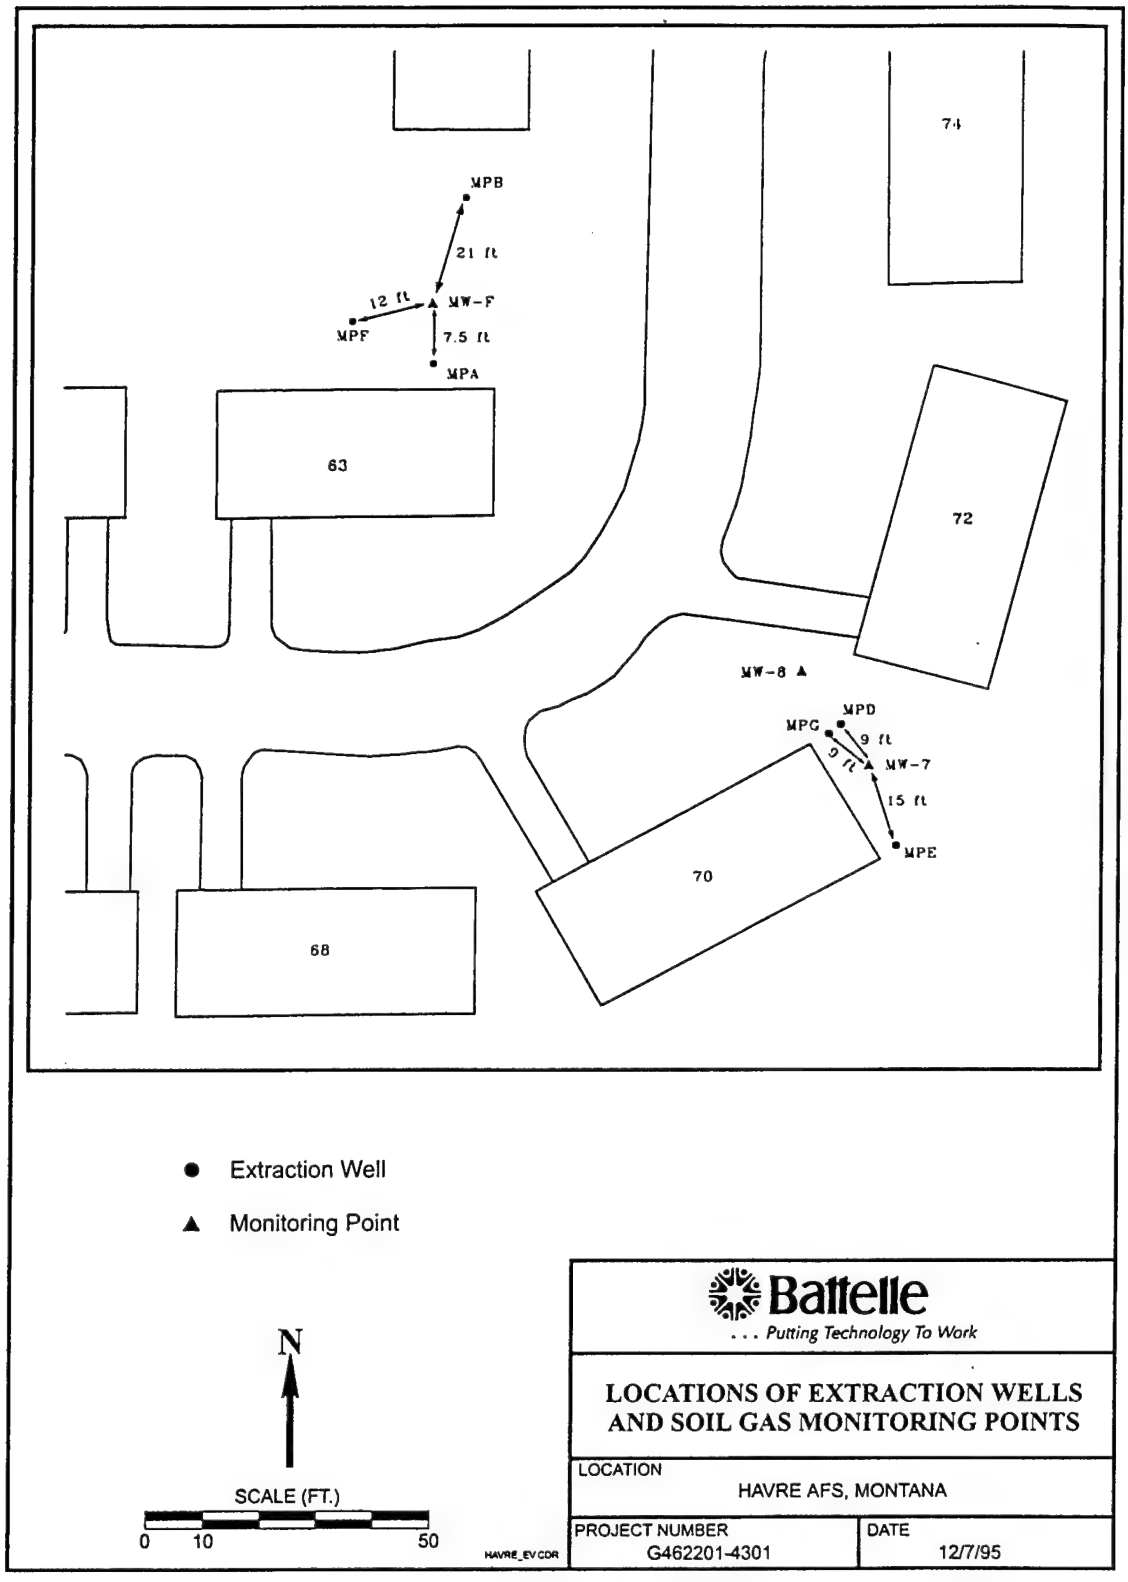

Figure 1. **Schematic Diagram Showing Locations of Monitoring Wells and Monitoring Points at the Base Housing Area, Havre AFS, MT**

could no longer be reduced. The rate of increase in the thickness of the floating LNAPL layer was monitored using the oil/water interface probe for approximately 32 hours.

3.1.2 Well Construction Details

A short-term bioslurper pump test was conducted at existing monitoring well MW-F. The well is constructed of 4-inch-diameter, schedule 40 polyvinyl chloride (PVC). The monitoring well was constructed with a total depth of 19 ft and 15 ft of screen.

3.1.3 Soil Gas Monitoring Point Installation

Four monitoring points were installed in the area of monitoring well MW-F and were labeled MPA, MPB, MPC, and MPF. The locations of the monitoring points are illustrated in Figures 1 and 2.

The monitoring points consisted of sets of ¼-inch tubing, with 1-inch-diameter, 6-inch-long screened areas. The screened lengths were positioned at the appropriate depths, and the annular space corresponding to the screened length was filled with silica sand. The interval between the screened lengths was filled with bentonite clay chips, as was the space from the top of the shallowest screened length to the ground surface. After placement, the bentonite clay was hydrated with water to expand the chips and provide a seal. The monitoring points were installed at depths as follows:

- Monitoring point MPA was installed at a depth of 11.5 ft into a 6-inch diameter borehole. The monitoring point was screened to two depths: 8.0 to 8.5 and 10.0 to 10.5 ft.
- Monitoring point MPB was installed at a depth of 17.5 ft into a 6-inch diameter borehole. The monitoring point was screened to two depths: 10.5 to 11.0 and 15.0 to 15.5 ft.
- Monitoring point MPF was installed at a depth of 14.0 ft into a 6-inch diameter borehole. The monitoring point was screened to two depths: 13.5 to 14.0 and 8.5 to 9.0 ft.

Monitoring point MPC was abandoned because no contamination was evident in the boring. After installation of the monitoring points, initial soil gas measurements were taken with a GasTechtor

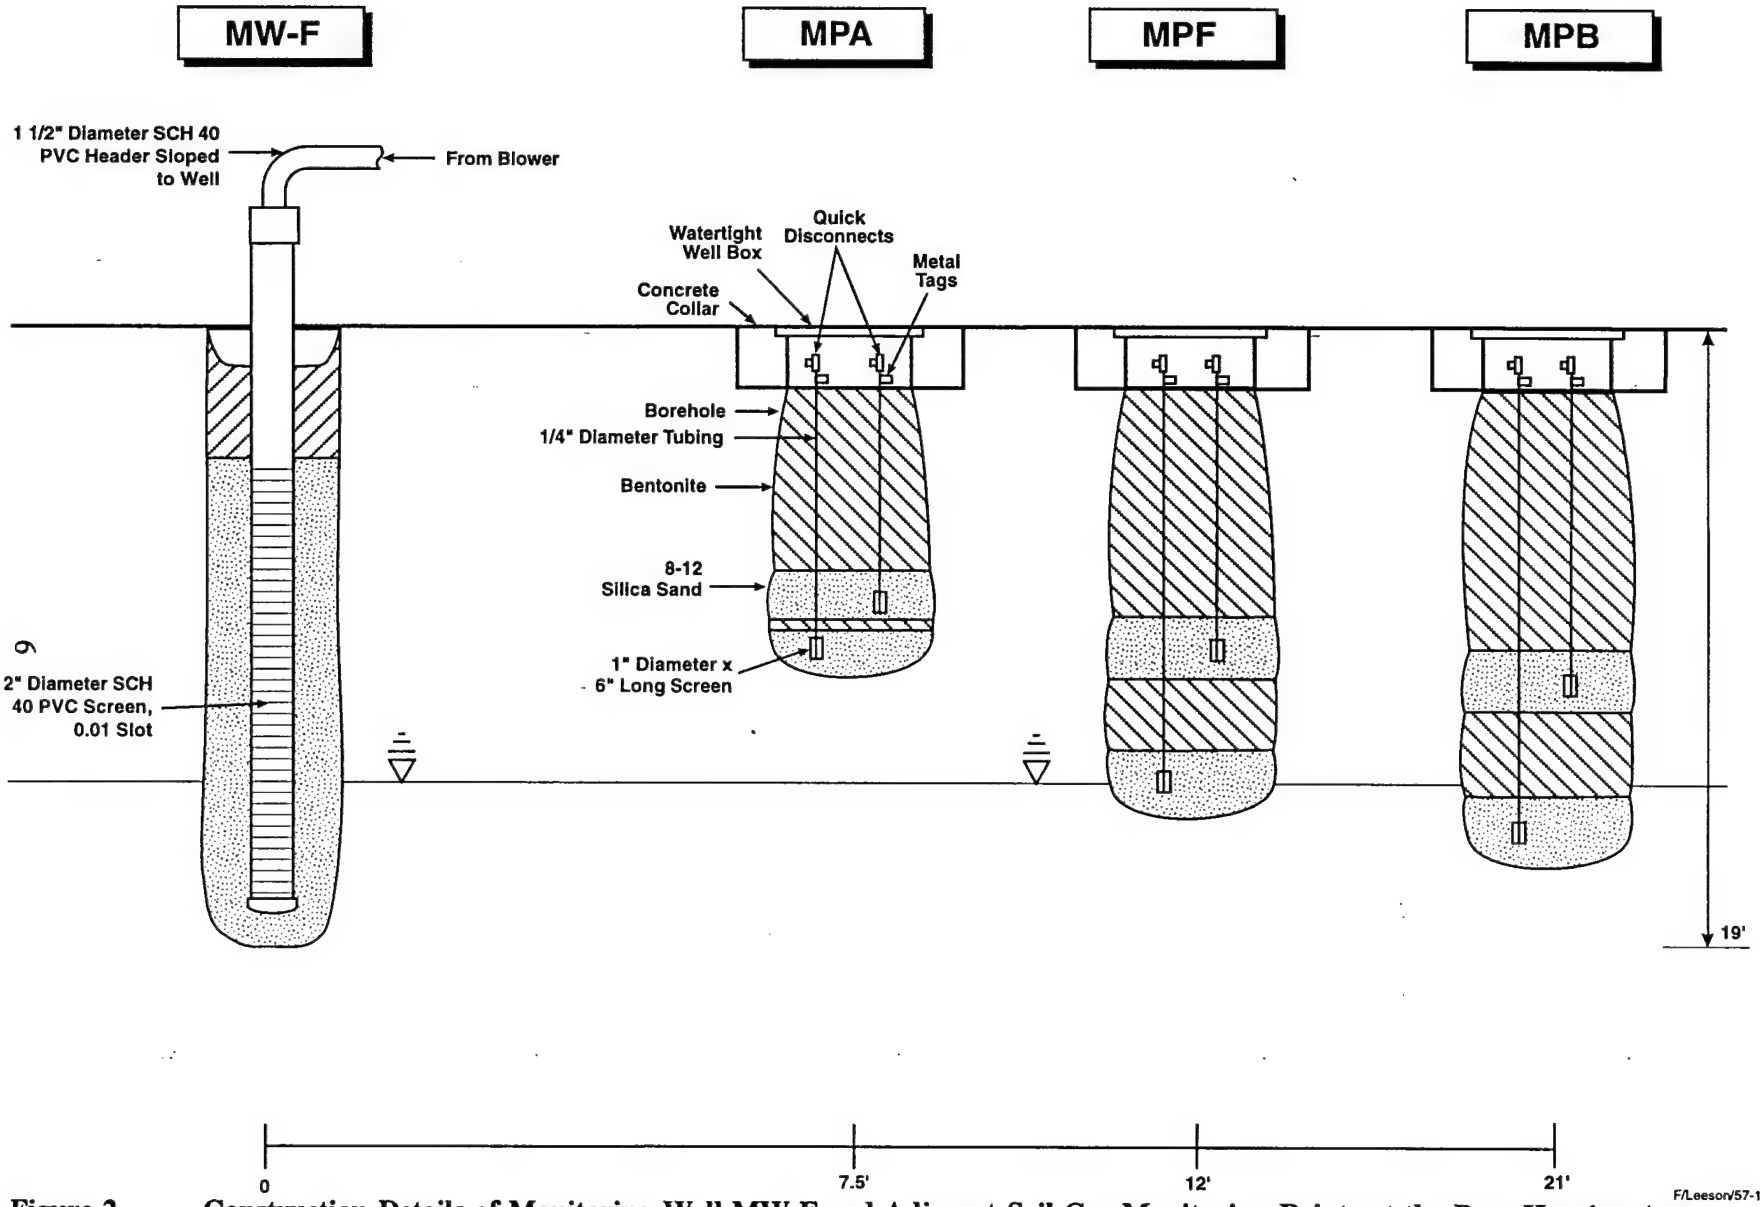

Figure 2. **Construction Details of Monitoring Well MW-F and Adjacent Soil Gas Monitoring Points at the Base Housing Area, Havre AFS, MT**

portable O_2/CO_2 meter and a GasTech Trace-Techtor portable hydrocarbon meter. In general, oxygen limitation was observed at the deeper depths of monitoring points, except at monitoring point MPB. Oxygen concentrations ranging from 0% to 1.0% were found in MPA and MPF at depths of 10.0 ft and greater (Table 1).

Table 1. Initial Soil Gas Compositions at Site 1, the Base Housing Area, Havre AFS, MT

Monitoring Point	Depth (ft)	Oxygen (%)	Carbon Dioxide (%)	TPH (ppmv)
MPA	8.0-8.5	10.0	2.5	600
	10.0-10.5	0.0	14.0	300
MPB	10.5-11.0	19.0	0.50	40
	15.0-15.5	16.5	3.0	195
MPF	8.5-9.0	20.0	0.80	72
	13.5-14.0	1.0	16.0	>10,000

3.1.4 Soil Sampling and Analysis

One soil sample was collected during the installation of monitoring point MPA and was labeled HAV-MPA-10.0'-10.5'. The soil sample was collected in a brass sleeve using a split-spoon sampler. The sample was placed in an insulated cooler, chain-of-custody records and shipping papers were completed, and the sample was sent to Alpha Analytical, Inc., in Sparks, Nevada. The sample was analyzed for BTEX, bulk density, moisture content, particle size, porosity, and TPH. The laboratory analytical report is provided in Appendix B.

3.1.5 LNAPL Recovery Testing

3.1.5.1 System Setup

The bioslurping pilot test system is a trailer-mounted mobile unit. The vacuum pump (Atlantic Fluidics Model A100, 7.5-hp liquid ring pump), oil/water separator, and required support

equipment are carried to the test location on a trailer. The trailer was located near monitoring well MW-F, the well cap was removed, a coupling and tee were attached to the top of the well, and the slurper tube was lowered into the well. The slurper tube was attached to the vacuum pump. Different configurations of the tee and the placement depth of the slurper tube allow for simulation of skimmer pumping, operation in the bioslurping configuration, or simulation of drawdown pumping. Extracted groundwater was treated by passing the effluent through an oil/water separator and allowed to settle in a 500 gallon tank. The groundwater was then discharged to the sanitary sewer.

A brief system startup test was performed prior to LNAPL recovery testing to ensure that all system components were working properly. The system checklist is provided in Appendix C. All site data and field testing information were recorded in a field notebook and then transcribed onto pilot test data sheets provided in Appendix D.

3.1.5.2 Bioslurper Pump Test

Prior to test initiation, depths to LNAPL and groundwater were measured. The slurper tube was then set at the LNAPL/groundwater interface. The PVC connecting tee was removed, sealing the wellhead and allowing the pump to establish a vacuum in the well (Figure 3). A pressure gauge was installed at the wellhead to measure the vacuum inside the extraction well. The liquid ring pump and oil/water separator were primed with known amounts of groundwater to ensure that any LNAPL or groundwater entering the system could be quantified. The flow totalizers for the LNAPL and aqueous effluent were zeroed, and the liquid ring pump was started on October 11, 1995, to begin the bioslurper pump test. The test was operated continuously for approximately 45 hours. The LNAPL and groundwater extraction rates were monitored throughout the test, as were all other relevant data for the bioslurper pump test. Test data sheets are provided in Appendix D.

3.1.6 Soil Gas Permeability Testing

Soil gas permeability test data were collected during the bioslurper pump test in monitoring well MW-F. Before a vacuum was established in the extraction well, the initial soil gas pressures at the monitoring points were recorded. The start of the bioslurper pump test created a steep pressure drop in the extraction well which was the starting point for the soil gas permeability testing. Soil gas pressures were measured at each of the three monitoring points at all depths to track the rate of

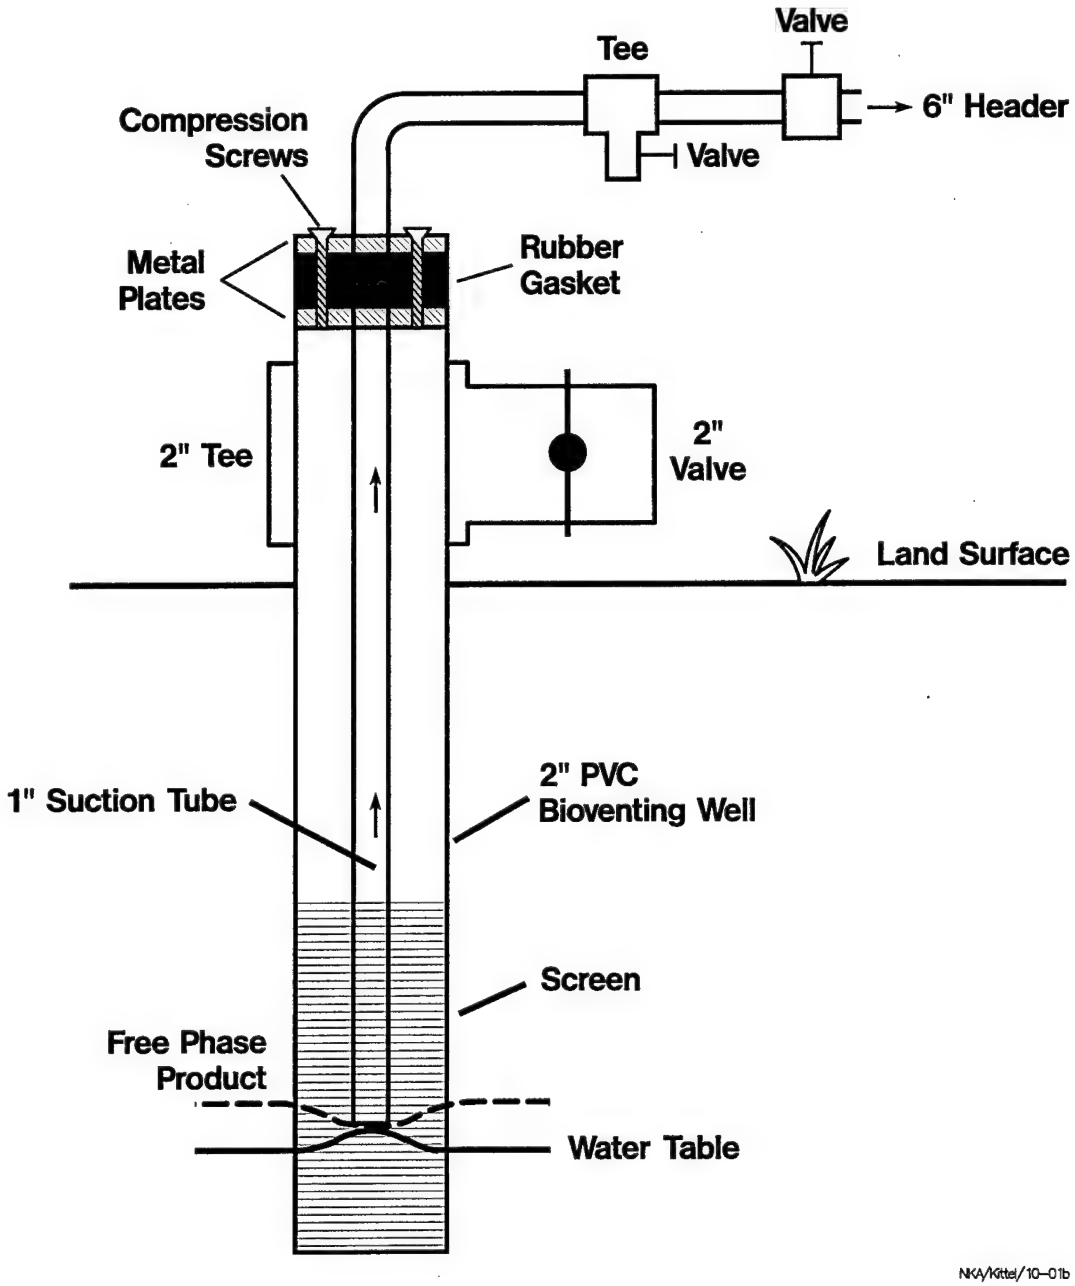

Figure 3. Slurper Tube Placement and Valve Position for the Bioslurper Pump Test

outward propagation of the pressure drop in the extraction well. Soil gas pressure data were collected frequently during the first 20 minutes of the test. The soil gas pressures were recorded throughout the bioslurper pump test to determine the bioventing radius of influence. Test data are provided in Appendix E.

3.2 Site 2: Activities at Monitoring Well MW-7

3.2.1 Initial LNAPL/Groundwater Measurements and Baildown Testing

Monitoring well MW-7 was evaluated for use in the bioslurper pilot testing. Initial depths to LNAPL and to groundwater were measured using an oil/water interface probe (ORS Model #1068013). LNAPL was removed from the well with a peristaltic pump until the LNAPL thickness could no longer be reduced. The rate of increase in the thickness of the floating LNAPL layer was monitored using the oil/water interface probe for approximately 25 hours.

3.2.2 Well Construction Details

Existing monitoring well MW-7 was selected for use in the bioslurper pilot testing. The well is constructed of 4-inch-diameter, schedule 40 PVC. Screened length of the well is unknown, but is likely similar to other wells in the area, with a total depth of approximately 19 ft and 10 to 15 ft of screen.

3.2.3 Soil Gas Monitoring Point, Thermocouple, and DataWrite Oxygen Sensor Installation

Three monitoring points were installed in the area of monitoring well MW-7 and were labeled MPD, MPE, and MPG. The locations of the monitoring points are illustrated in Figures 1 and 4.

The monitoring points consisted of sets of ¼-inch tubing, with 1-inch-diameter, 6-inch-long screened areas. The screened lengths were positioned at the appropriate depths, and the annular space corresponding to the screened length was filled with silica sand. The interval between the screened lengths was filled with bentonite clay chips, as was the space from the top of the shallowest screened length to the ground surface. After placement, the bentonite clay was hydrated with water to expand the chips and provide a seal. The monitoring points were installed at depths as follows:

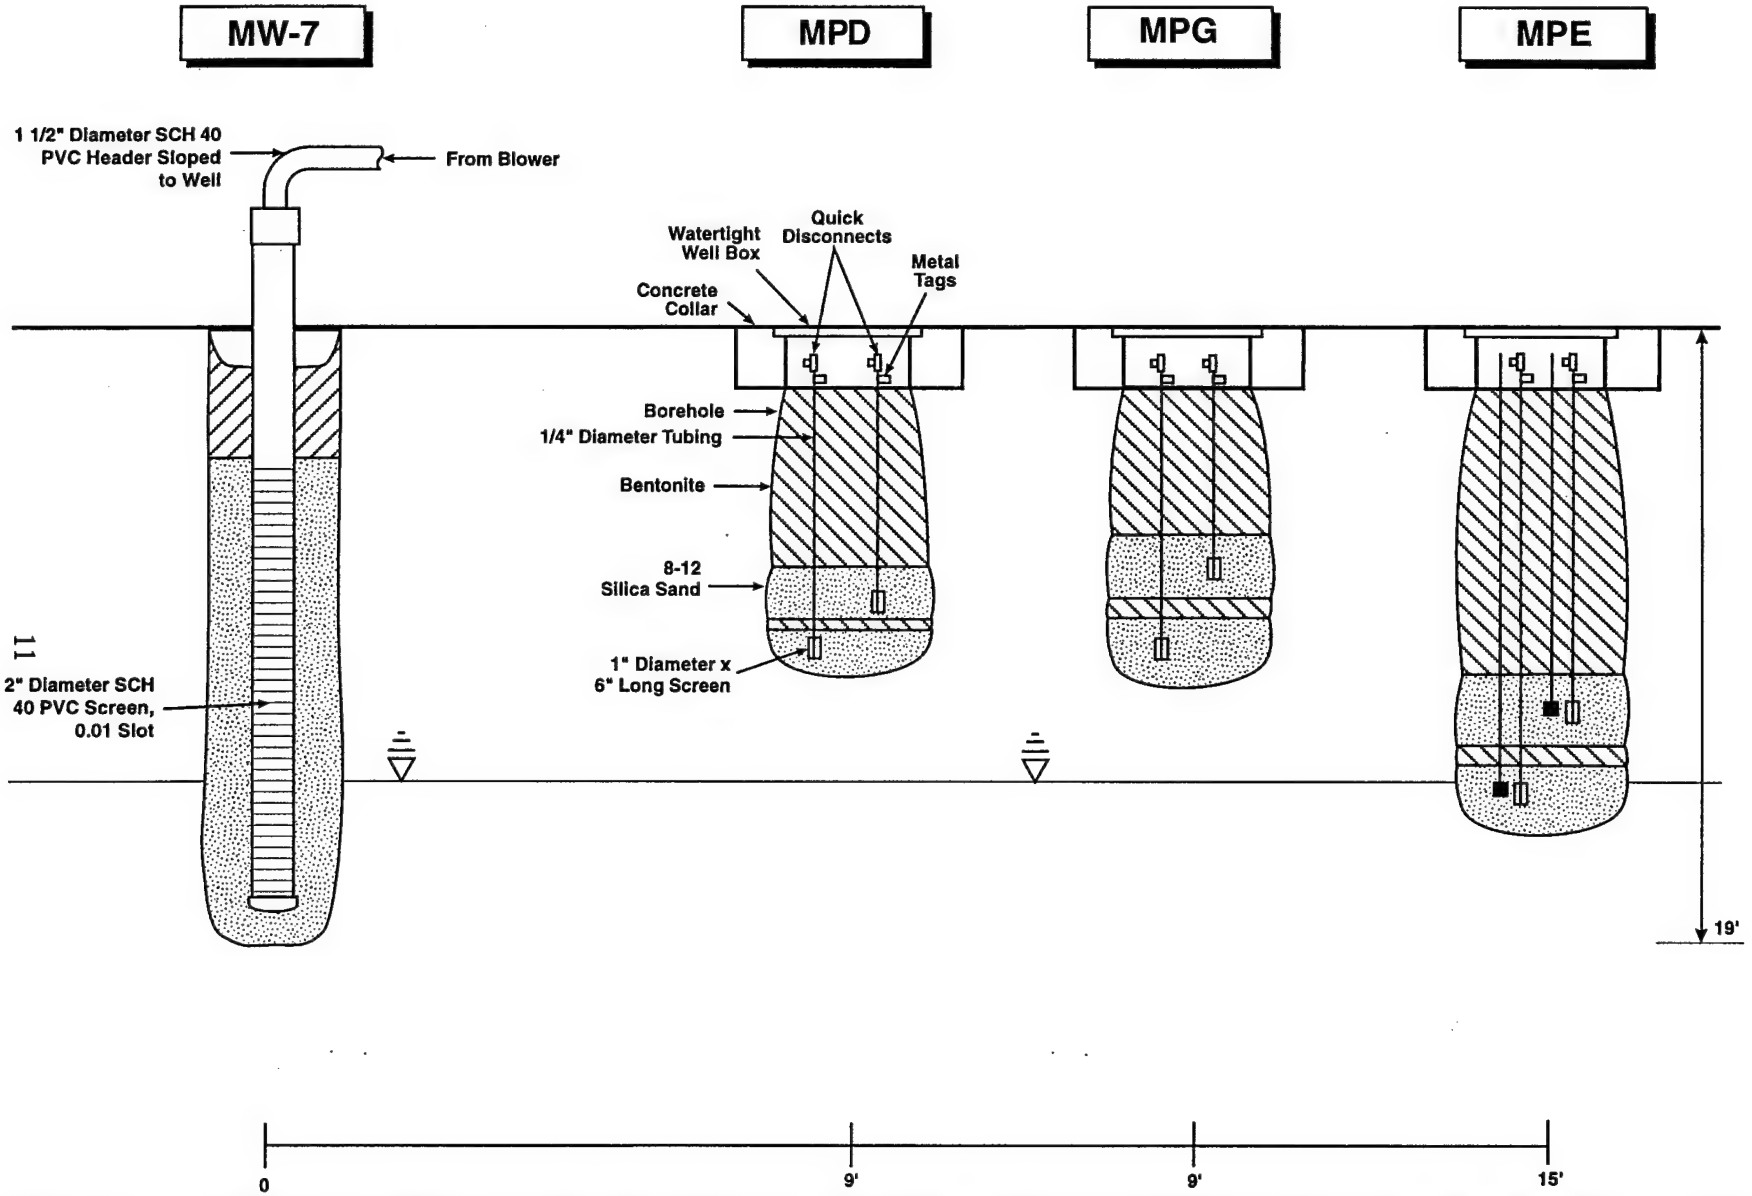

Figure 4. **Construction Details of Monitoring Well MW-7 and Adjacent Soil Gas Monitoring Points at the Base Housing Area, Havre AFS, MT**

F/Leeson/57-2

- Monitoring point MPD was installed at a depth of 11.0 ft into a 6-inch diameter borehole. The monitoring point was screened to two depths: 8.0 to 8.5 and 10.0 to 10.5 ft.

- Monitoring point MPE was installed at a depth of 16.5 ft into a 6-inch diameter borehole. The monitoring point was screened to two depths: 11.5 to 12.0 and 14.0 to 14.5 ft.

- Monitoring point MPG was installed at a depth of 11.0 ft into a 6-inch diameter borehole. The monitoring point was screened to two depths: 7.0 to 7.5 and 10.0 to 10.5 ft.

Type J thermocouples were installed in monitoring point MPE at depths of 12 and 14 ft. DataWrite Research oxygen sensors were installed in monitoring point MPG at depths of 7.5 and 10.5 ft. The oxygen sensors were on-line from October 13 through 23, 1995 and from December 4 through 7, 1995.

The DataWrite oxygen sensors consist of an in situ oxygen probe, signal transfer line, and an aboveground data logger. DataWrite software was installed to a personal computer to calibrate, program, and initiate operation of the sensors. The in situ sensors respond to oxygen concentrations in the soil gas and generate a millivolt signal reflecting that concentration. Each sensor was calibrated before being installed in the vadose zone by producing a response to the atmospheric oxygen level of 21%. The calibration factor (sensor voltage divided by 21) was then retained by the sensor's data logger. Future oxygen concentrations were calculated by applying that calibration factor to the millivolt signal from the sensor.

The DataWrite oxygen sensor was programmed through the data logger to generate oxygen measurements on a temporal basis. The millivolt signal from the two sensors installed at monitoring point MPG was recorded every 30 minutes. The data logger stored these millivolt signals and their resulting oxygen concentrations. The data were downloaded daily to a Hewlett Packard 200LX Palmtop personal computer. Two files were established during this downloading process: (1) a raw data file with recording number, date, time, elapsed time, percent oxygen concentrations, and millivolt signal, and (2) a chart that graphically presented the percent oxygen concentrations over time.

After installation of the monitoring points, initial soil gas measurements were taken with a GasTechtor portable O_2/CO_2 meter and a GasTech Trace-Techtor portable hydrocarbon meter. In general, oxygen limitation was observed at the deeper depths of monitoring points, except at

monitoring point MPE. Oxygen concentrations ranging from 0.5% to 4.0% were found in MPD and MPG at depths of 10.0 ft (Table 2).

Table 2. Initial Soil Gas Compositions at Site 2, the Base Housing Area, Havre AFS, MT

Monitoring Point	Depth (ft)	Oxygen (%)	Carbon Dioxide (%)	TPH (ppmv)
MPD	8-8.5	12.5	7.5	320
	10-10.5	0.50	17.5	840
MPE	11.5-12.0	17.0	4.0	275
	14-14.5	15.5	4.5	350
MPG	7.0-7.5	17.0	3.0	240
	10.0-10.5	4.0	12.0	720

3.2.4 Soil Sampling and Analysis

One soil sample was collected during the installation of monitoring point MPD and was labeled HAV-MPD-10.0'-10.5'. The soil sample was collected in a brass sleeve using a split-spoon sampler. The sample was placed in an insulated cooler, chain-of-custody records and shipping papers were completed, and the sample was sent to Alpha Analytical, Inc., in Sparks, Nevada. The sample was analyzed for BTEX, bulk density, moisture content, particle size, porosity, and TPH. The laboratory analytical report is provided in Appendix B.

3.2.5 LNAPL Recovery Testing

3.2.5.1 System Setup

The bioslurping pilot test system is the same as described in Section 3.1.5.1. A brief system startup test was performed prior to LNAPL recovery testing to ensure that all system components were working properly. The system checklist is provided in Appendix C. All site data and field

testing information were recorded in a field notebook and then transcribed onto pilot test data sheets provided in Appendix D.

3.2.5.2 Initial Skimmer Pump Test

Prior to test initiation, depths to LNAPL and groundwater were measured. The slurper tube was then set at the LNAPL/groundwater interface with the wellhead open to the atmosphere via a PVC connecting tee (Figure 5). The liquid ring pump and oil/water separator were primed with known amounts of groundwater to ensure that any LNAPL or groundwater entering the system could be quantified. The flow totalizers for the LNAPL and aqueous effluent were zeroed, and the liquid ring pump was started on October 11, 1995, to begin the skimmer pump test. The test was operated continuously for approximately 39 hours. The LNAPL and groundwater extraction rates were monitored throughout the test, as were all other relevant data for the skimmer pump test. Test data sheets are provided in Appendix D.

An LNAPL sample was collected during the initial skimmer test and was labeled HAV-FUEL-MW7. The sample was sent to Alpha Analytical, Inc., Sparks, Nevada for analysis of BTEX and boiling point fractionation.

3.2.5.3 Bioslurper Pump Test

Upon completion of the skimmer pump test, preparations were made to begin the bioslurper pump test. Prior to test initiation, depths to LNAPL and groundwater were measured. The slurper tube was then set at the LNAPL/groundwater interface, as in the skimmer pump test. However, in contrast to the skimmer pump test, the PVC connecting tee was removed, sealing the wellhead and allowing the pump to establish a vacuum in the well (Figure 3). A pressure gauge was installed at the wellhead to measure the vacuum inside the extraction well. The liquid ring pump and oil/water separator were primed with known amounts of groundwater to ensure that any LNAPL or groundwater entering the system could be quantified. The flow totalizers for the LNAPL and aqueous effluent were zeroed, and the liquid ring pump was started on October 14, 1995, to begin the bioslurper pump test. The test was initiated approximately 15 hours after the skimmer pump test and was operated continuously for approximately 98 hours. The LNAPL and groundwater extraction

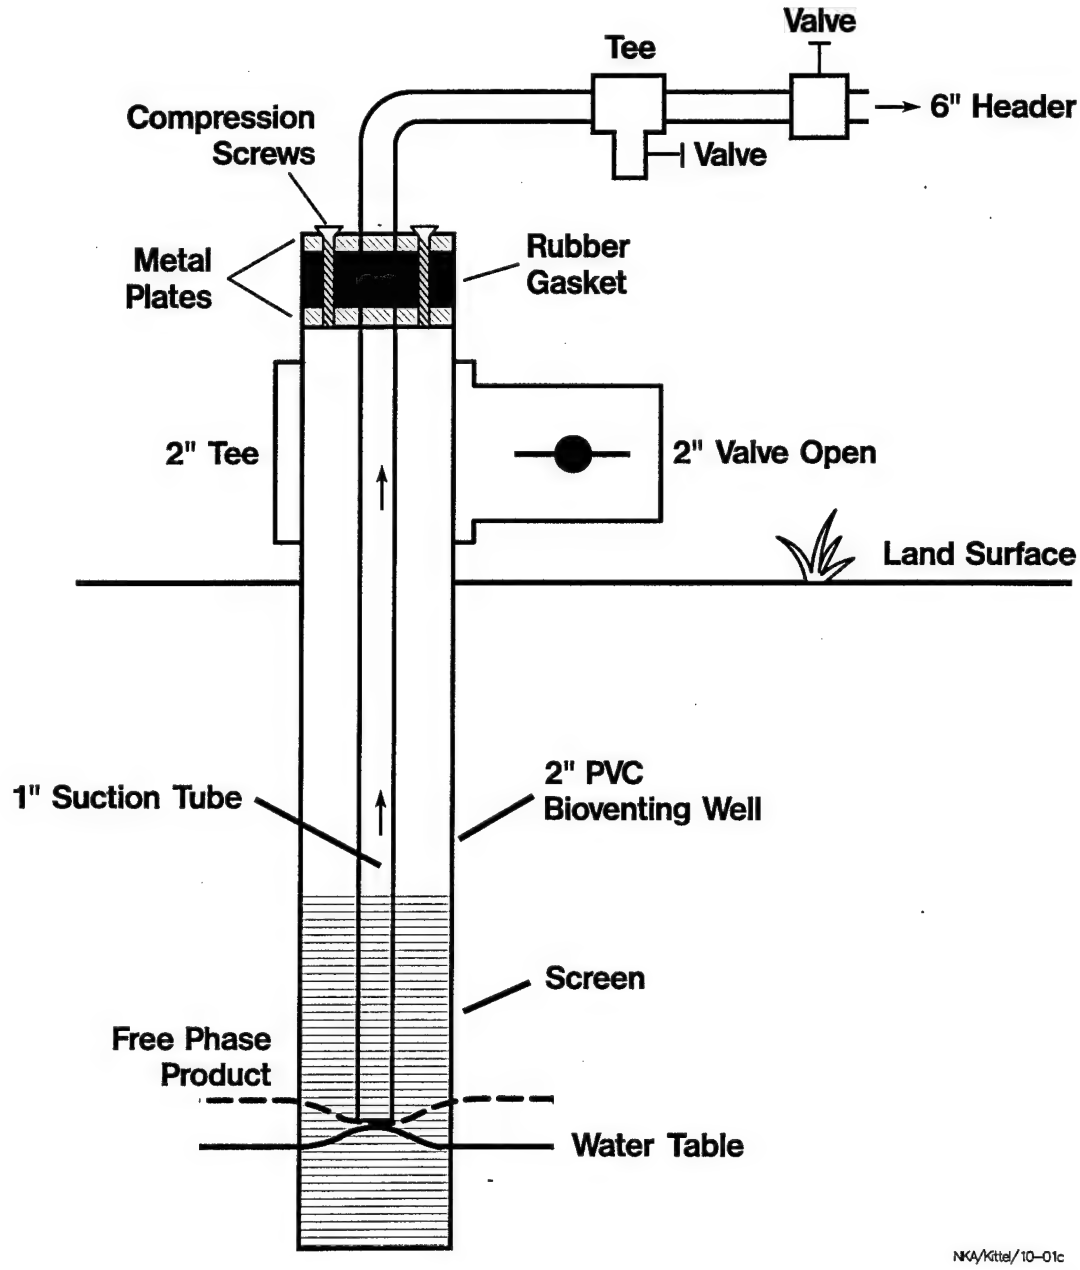

Figure 5. Slurper Tube Placement and Valve Position for the Skimmer Pump Test

rates were monitored throughout the test, as were all other relevant data for the bioslurper pump test. Test data sheets are provided in Appendix D.

3.2.5.4 Drawdown Pump Test

Upon completion of the bioslurper pump test, preparations were made to begin the drawdown pump test. Prior to test initiation, depths to LNAPL and groundwater were measured. The slurper tube was then set so that the tip was 17 inches below the oil/water interface with the PVC connecting tee open to the atmosphere (Figure 6). The liquid ring pump and oil/water separator were primed with known amounts of groundwater to ensure that any LNAPL or groundwater entering the system could be quantified. The flow totalizers for the LNAPL and aqueous effluent were zeroed, and the liquid ring pump was started on October 18, 1995, to begin the drawdown pump test. The test was initiated approximately 1 hour after the bioslurper pump test and was operated continuously for 47 hours. The LNAPL and groundwater extraction rates were monitored throughout the test, as were all other relevant data for the drawdown pump test. Test data sheets are provided in Appendix D.

3.2.5.5 Second Skimmer Pump Test

Upon completion of the drawdown pump test, preparations were made to begin the second skimmer pump test. Prior to test initiation, depths to LNAPL and groundwater were measured. The valve and slurper tube configuration were identical to that used for the initial skimmer pump test. The liquid ring pump and oil/water separator were primed with known amounts of groundwater to ensure that any LNAPL or groundwater entering the system could be quantified. The flow totalizers for the LNAPL and aqueous effluent were zeroed, and the liquid ring pump was started on October 20, 1995, to begin the second skimmer pump test. The test was initiated approximately 7 hours after the drawdown pump test and was operated continuously for 27 hours. The LNAPL and groundwater extraction rates were monitored throughout the test, as were all other relevant data for the bioslurper pump test. Test data sheets are provided in Appendix D.

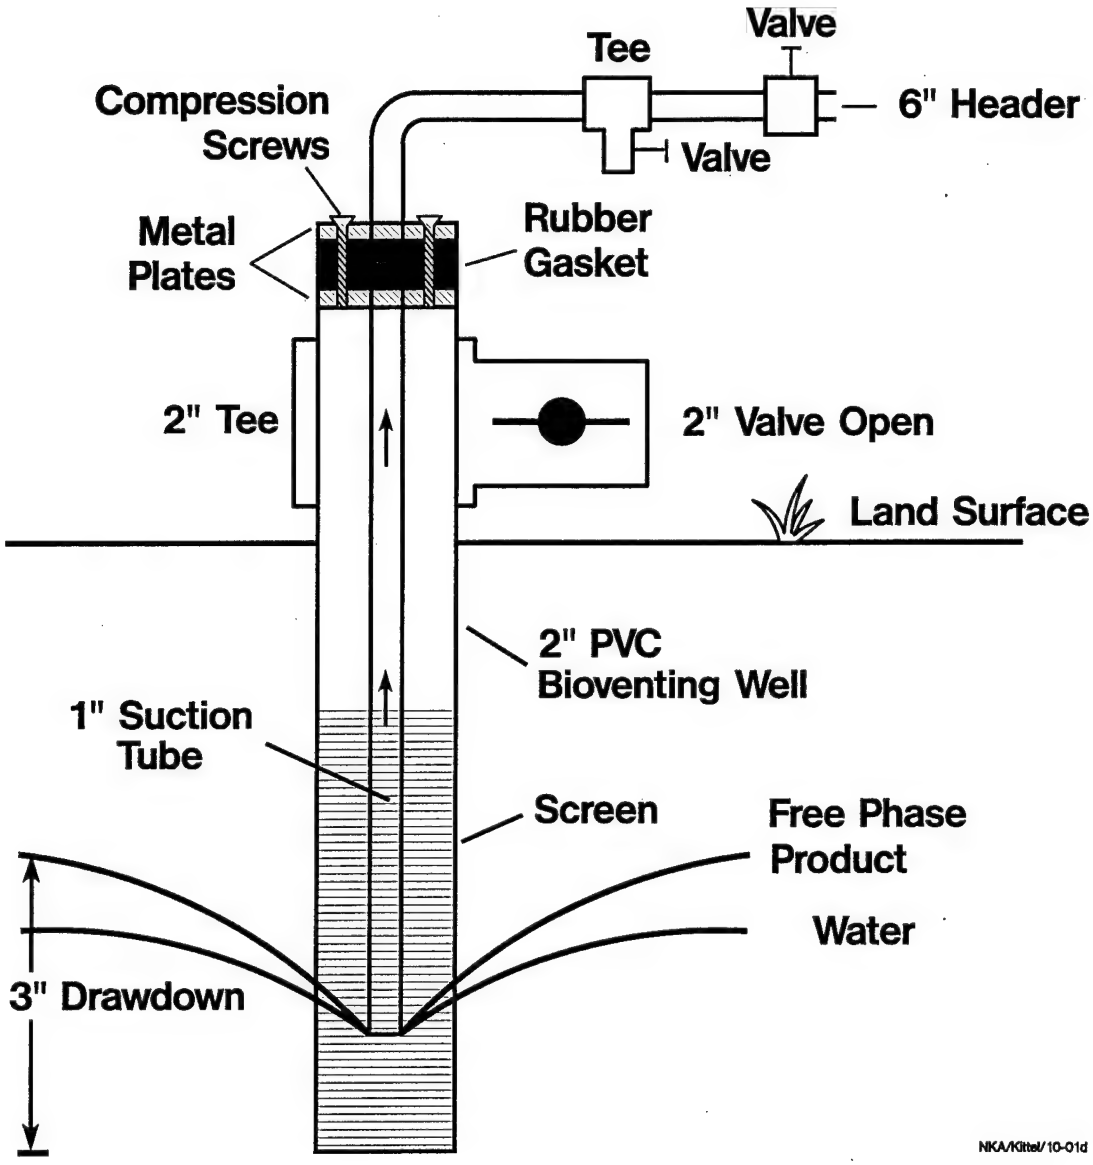

Figure 6. Slurper Tube Placement and Valve Position for the Drawdown Pump Test

3.2.5.6 Off-Gas Sampling and Analysis

A soil gas sample was collected from the bioslurper off-gas during the bioslurper pump test. The sample was collected in a Tedlar™ bag and transferred to a Summa™ canister. The sample was labeled HAV-Stack Gas and sent under chain of custody to Air Toxics, Ltd., in Rancho Cordova, California, for analyses of BTEX and TPH.

3.2.5.7 Groundwater Sampling and Analysis

Two groundwater samples were collected during the bioslurper pump test. Samples were collected from the oil/water separator and were labeled HAV-OWS-Water-Samp1 and HAV-OWS-Water-Samp2. Samples were collected in 40-mL VOA vials containing HCl preservative. Samples were checked to ensure no headspace was present and were then shipped on ice and sent under chain of custody to Alpha Analytical, Inc., in Sparks, Nevada for analyses of BTEX and TPH.

3.2.6 Soil Gas Permeability Testing

Soil gas permeability test data were collected during the bioslurper pump test in monitoring well MW-7. Before a vacuum was established in the extraction well, the initial soil gas pressures at the monitoring points were recorded. The start of the bioslurper pump test created a steep pressure drop in the extraction well which was the starting point for the soil gas permeability testing. Soil gas pressures were measured at each of the three monitoring points at all depths to track the rate of outward propagation of the pressure drop in the extraction well. Soil gas pressure data were collected frequently during the first 20 minutes of the test. The soil gas pressures were recorded throughout the bioslurper pump test to determine the bioventing radius of influence. Test data are provided in Appendix E.

3.2.7 In Situ Respiration Testing

Air containing approximately 3.7% helium was injected into four monitoring points for approximately 23 hours beginning on October 19, 1995. The setup for the in situ respiration test is described in the *Test Plan and Technical Protocol a Field Treatability Test for Bioventing* (Hinchee et al., 1992). A ½-hp diaphragm pump was used for air and helium injection. Air and helium were injected through the following monitoring points at the depths indicated: MPD-8.0′, MPD-10.0′, MPE-11.5′, and MPG-10.0′. After the air/helium injection was terminated, soil gas concentrations of oxygen, carbon dioxide, TPH, and helium were monitored periodically. The respiration test was terminated on October 22, 1995. Oxygen utilization and biodegradation rates were calculated as described in Hinchee et al. (1992). Raw data for these tests are presented in Appendix F.

Helium concentrations were measured during the in situ respiration test to quantify helium leakage to or from the surface around the monitoring points. Helium loss over time is attributable to either diffusion through the soil or leakage. A rapid drop in helium concentration usually indicates leakage. A gradual loss of helium along with a first-order curve generally indicates diffusion. As a rough estimate, the diffusion of gas molecules is inversely proportional to the square root of the molecular weight of the gas. Based on molecular weights of 4 for helium and 32 for oxygen, helium diffuses approximately 2.8 times faster than oxygen, or the diffusion of oxygen is 0.35 times the rate of helium diffusion. As a general rule, we have found that if helium concentrations at test completion are at least 50 to 60% of the initial levels, measured oxygen uptake rates are representative. Greater helium loss indicates a problem, and oxygen utilization rates are not considered representative.

4.0 RESULTS

This section documents the results of the site characterization, the comparative LNAPL recovery pump test, and other supporting tests conducted at Havre AFS.

4.1 Site 1: Results at Monitoring Well MW-F

4.1.1 Baildown Test Results

Results from the baildown test in monitoring well MW-F is presented in Table 3. A total volume of 9.5 L (2.5 gallons) was removed by hand bailing from monitoring well MW-F. The LNAPL thickness did not recover to initial levels by the end of the 32-hour test period, which indicated that the well may not be suitable for bioslurping. Therefore, only a short-term bioslurper pump test was conducted.

4.1.2 Soil Sample Analyses

Table 4 shows the BTEX and TPH concentrations measured in the soil sample collected from Site 1 at the Base Housing Area. BTEX and TPH concentrations were relatively high at a total BTEX concentration of 2.9 mg/kg and a TPH concentration of 6,700 mg/kg. Benzene and toluene were below detection limits. The results of the physical characterization of the soil is presented in Table 5.

4.1.3 Bioslurper Pump Test Results

LNAPL recovery rates were relatively low during the bioslurper pump test. A total of 2.4 gallons of LNAPL and 400 gallons of groundwater were extracted during the bioslurper pump test, with daily average recovery rates of 1.3 gallons/day for LNAPL and 210 gallons/day for groundwater (Table 6).

Soil gas concentrations were measured at monitoring points during the bioslurper pump test to determine whether the vadose zone was being oxygenated. Oxygen concentrations increased significantly only at monitoring point MPA (Table 7).

4.1.4 Bioventing Analyses: Soil Gas Permeability and Radius of Influence Testing

The radius of influence is calculated by plotting the log of the pressure change at a specific monitoring point versus the distance from the extraction well. The radius of influence is then defined

Table 3. Results of Baildown Testing in Monitoring Well MW-F

[1] One hour after bioslurper pump shut off.

as the distance from the extraction well where 0.1 inch of H_2O can be measured. Based on this definition, the radius of influence during the bioslurper pump test at monitoring well MW-F was approximately 18 ft (Figure 7).

4.2 Site 2: Results at Monitoring Well MW-7

4.2.1 Baildown Test Results

Results from the baildown test in monitoring well MW-7 is presented in Table 8. A total volume of 1.1 L (0.29 gallons) was removed by hand bailing from monitoring well MW-7. The LNAPL thickness recovered rapidly to approximately initial levels by the end of the 25-hour test period. These results indicated that monitoring well MW-7 was suitable for bioslurper field testing.

4.2.2 Soil Sample Analyses

Table 9 shows the BTEX and TPH concentrations measured in soil samples collected from the Base Housing Area. BTEX and TPH concentrations were relatively high with a total BTEX concentration of 35.3 mg/kg and a TPH concentration of 13,000 mg/kg. The results of the physical characterization of the soils are presented in Table 10.

4.2.3 LNAPL Pump Test Results

Results from the LNAPL pump tests are presented in the following sections. Due to the very low LNAPL recovery, a graph illustrating LNAPL recovery during each pump test was not prepared.

4.2.3.1 Initial Skimmer Pump Test Results

A total of 0.73 gallons of LNAPL was recovered during this test, with an average recovery rate of 0.45 gallons/day (Table 11). A total of 1.6 gallons of groundwater was extracted with an average extraction rate of 0.99 gallons/day (Table 11).

4.2.3.2 Bioslurper Pump Test Results

The LNAPL thickness prior to the bioslurper pump test was 0.060 ft (Table 12). LNAPL recovery rates was relatively low during the bioslurper pump test. A total of 0.55 gallons of LNAPL and 304 gallons of groundwater were extracted during the bioslurper pump test, with daily average recovery rates of 0.14 gallons/day for LNAPL and 76 gallons/day for groundwater (Table 11). The vacuum-exerted wellhead pressure on monitoring well MW-7 ranged from 5 to 9 inches of mercury throughout the bioslurper pump test.

Soil gas concentrations were measured at monitoring points during the bioslurper pump test to determine whether the vadose zone was being oxygenated. Oxygen concentrations increased significantly at all monitoring points in the vicinity of MW-7 (Table 13). These results correlate with radius of influence results from the soil gas permeability test.

Table 12. Depths to Groundwater and LNAPL Prior to Each Pump Test

Test	Test Start Date	Depth to LNAPL (ft)	Depth to Groundwater (ft)	LNAPL Thickness (ft)
Initial Skimmer Pump Test	10/13/95	NM	NM	NM

MPG-10.5′	4.00	17.50	18.00	19.25	19.50	18.90	18.50	21.00

[1] One hour after bioslurper pump shut off.

4.2.3.3 Drawdown Pump Test

LNAPL recovery was very low during the drawdown pump test. Very little LNAPL or groundwater was extracted, with totals of 0.15 gallons of LNAPL and 70 gallons of groundwater extracted (Table 11). These results demonstrate that operation of the bioslurper system in the drawdown mode was not an effective means of free-product recovery.

4.2.3.4 Second Skimmer Pump Test

Totals of 0.020 gallons of LNAPL and 1.7 gallons of groundwater were recovered during the second skimmer pump test, with daily average recovery rates of 0.018 gallons/day for LNAPL and 1.5 gallons/day for groundwater (Table 11). These results demonstrate that operation of the bioslurper system in the skimmer mode was not an effective means of free-product recovery.

4.2.4 Extracted Groundwater, LNAPL, and Off-Gas Analyses

Groundwater samples were collected during the bioslurper pump test. TPH concentrations were low, with average concentrations of 22 mg/L (Table 14). Benzene and toluene were present below detection limits. Ethylbenzene and xylenes were below 0.10 mg/L.

Off-gas samples from the bioslurper system also were collected during the bioslurper pump test. The results from the off-gas analyses are presented in Table 15. Given a vapor discharge rate of 23 scfm and using an concentration of 66 ppmv TPH and 0.021 ppmv benzene, approximately 0.89 lb/day of TPH and 0.00014 lb/day benzene was emitted to the air during the bioslurper pump test.

The composition of LNAPL is shown in Tables 16 and 17 in terms of BTEX concentrations and distribution of C-range compounds, respectively. The distribution of C-range compounds is shown graphically in Figure 8.

Table 14. BTEX and TPH Concentrations in Extracted Groundwater During the Bioslurper Pump Test at Havre AFS, MT

Parameter	Concentration (mg/L)

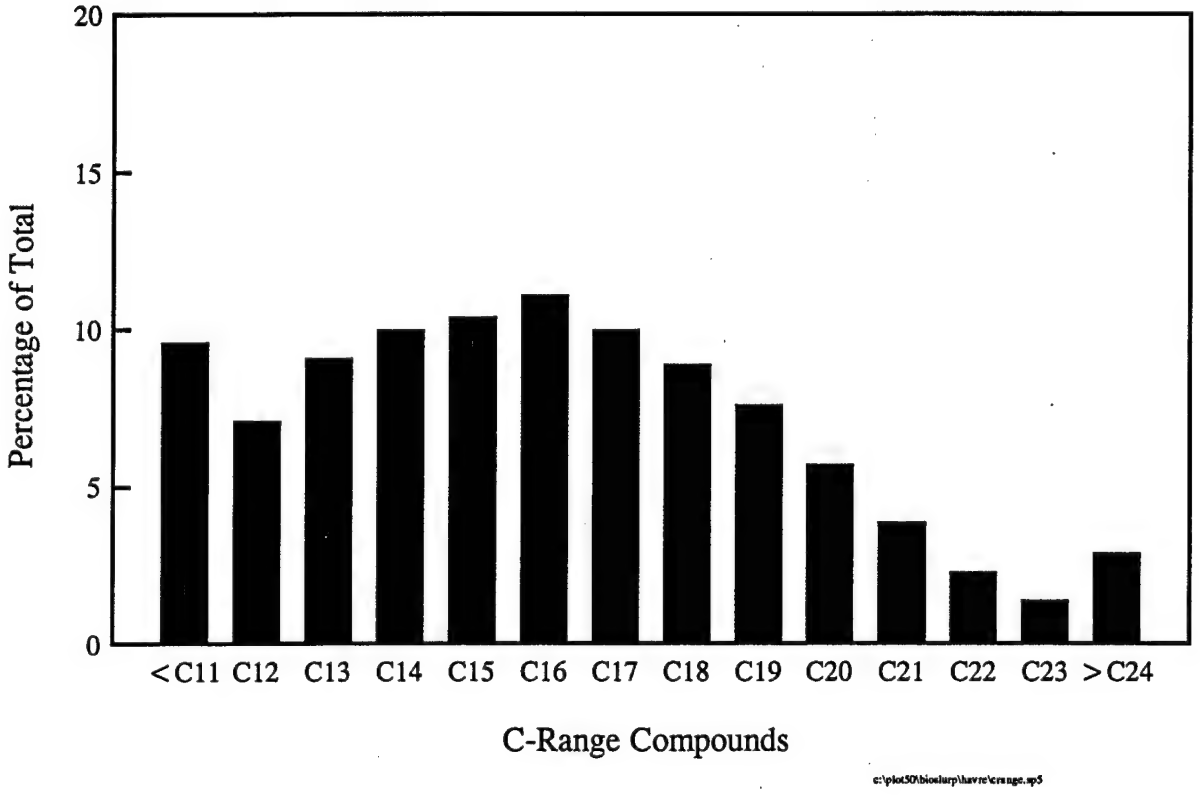

Figure 8. **Distribution of C-Range Compounds in Extracted LNAPL at the Base Housing Area, Havre AFS, MT**

4.2.5 Bioventing Analyses

4.2.5.1 Soil Gas Permeability and Radius of Influence

The radius of influence is calculated by plotting the log of the pressure change at a specific monitoring point versus the distance from the extraction well. The radius of influence is then defined as the distance from the extraction well where 0.1 inch of H_2O can be measured. Based on this definition, the radius of influence during the bioslurper pump test at monitoring well MW-7 was approximately 12 ft (Figure 9).

4.2.5.2 In Situ Respiration Test Results

Results from the in situ respiration test are presented in Table 18. Oxygen depletion was relatively fast, with oxygen utilization rates ranging from 0.083 to 0.45 $\%O_2$/hr. Biodegradation rates ranged from 1.3 to 7.2 mg/kg-day. No oxygen utilization was observed at monitoring point MPE-11.5′; however, soil gas at this monitoring point was not oxygen-depleted prior to the test. The helium concentration was relatively steady at monitoring points MPD; however, helium dropped below 50% of initial levels at monitoring point MPG before the end of the test, indicating that leakage and diffusion may have contributed to oxygen depletion at this monitoring point.

4.2.6 DataWrite Oxygen Sensor Evaluation

The two in situ oxygen sensors generated data over a period of 10 days in October and 3 days in December. Data from these tests is provided in Appendix G. During October, the sensor located 7.5 ft below ground surface operated as programmed and collected a full compliment of data points. Because of the close proximity of the sensor to the surface and low hydrocarbon concentrations, the values reported were generally close to atmospheric concentrations of oxygen. Slight decreases in oxygen levels were observed during the in situ respiration test, which correlated with measurements using field instruments. The sensor located 10.5 ft below ground surface performed properly for the first 7 days, except for abnormally high oxygen readings during the first 16 hours; however, during data transfer to the computer, a malfunction occurred, resulting in the loss of the data for the first week of operation. After this malfunction, data collected corresponded to data from field instruments.

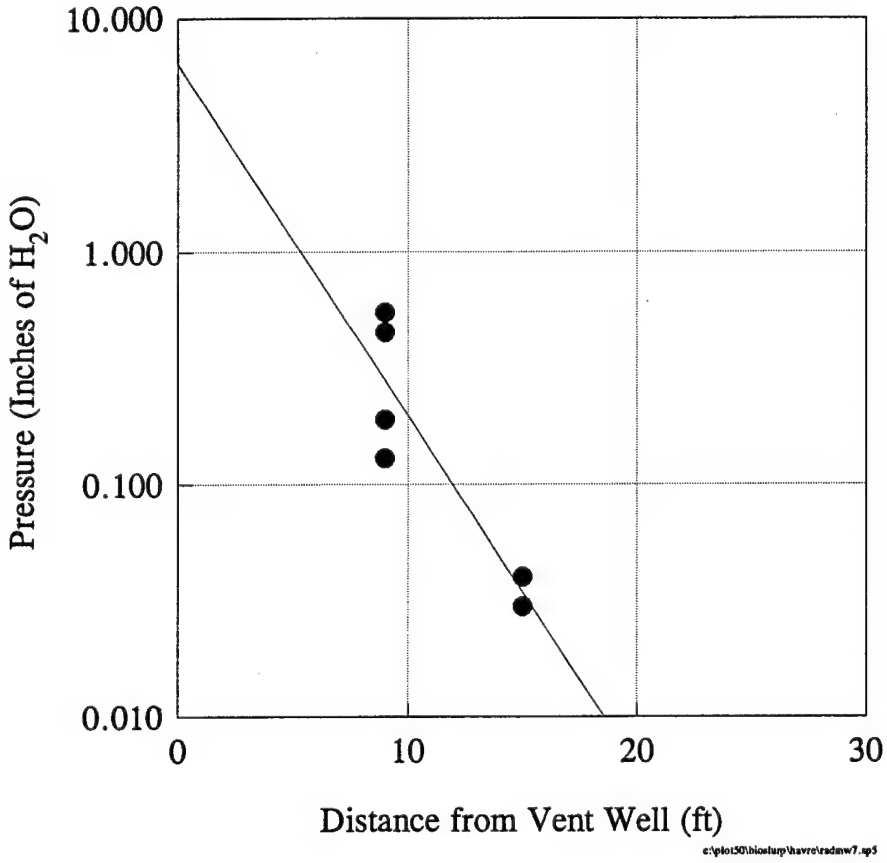

Figure 9. **Soil Gas Pressure Change as a Function of Distance During the Soil Gas Permeability Test at Monitoring Well MW-7**

Table 18. In Situ Respiration Test Results at the Base Housing Area, Havre AFS, MT

Monitoring Point	Oxygen Utilization Rate (%/hr)	Biodegradation Rate (mg/kg-day)
MPD-8.0′	0.083	1.3
MPD-10.0′	0.41	6.6
MPE-11.5′	0.0	0.0
MPG-10.0′	0.45	7.2

Correlation of all data collected with the oxygen sensors versus data collected with the GasTEch O_2/CO_2 meter generates a correlation coefficient of 0.9593. This data indicates that data collected with the oxygen sensors are very comparable to data collected with the field instruments.

A second test was conducted in December by turning off the blower and conducting a short in situ respiration test. Abnormally high oxygen readings again were obtained during initial operation. The data logger was reprogrammed and operated properly until the end of the test. Oxygen concentrations dropped slightly during the test and rose to near initial levels once the aeration was reinitiated. These results indicated that the oxygen sensors were generating useful data, but may require careful attention to ensure data loggers are functioning properly.

5.0 DISCUSSION

None of the LNAPL recovery techniques were successful at recovering free product. These results indicate that there is little free product present at the two sites or that it is relatively immobile. As a result, it was decided to install a bioventing system at both sites to remediate the vadose zone. Bioventing systems were configured to inject air into monitoring well MW-F at Site 1 and monitoring well MW-7 at Site 2.

Soil gas concentrations were measured at monitoring points during the bioslurper pump test to determine whether the vadose zone was being oxygenated. At Site 1, oxygen concentrations increased only at the closest monitoring point; however, based on radius of influence testing, it is likely that soil gas at greater distances will become oxygenated over time. At Site 2, all monitoring

points exhibited increased oxygen concentrations. These results correlated with results from the soil gas permeability test where a radius of influence of approximately 12 ft was determined. The radius of influence of the bioventing system potentially may be greater than 12 ft, since the system is configured for air injection. With the radius of influence from these systems, bioventing is treating the entire contaminant plume at both sites.

Implementation of bioslurping or any free-product recovery technique at the Havre AFS test site does not appear likely to facilitate enhanced recovery of LNAPL from the water table and simultaneous in situ biodegradation of hydrocarbons in the vadose zone via bioventing. A large volume of free product does not appear to be present; therefore, bioventing is recommended to remediate vadose zone contamination.

1.0 INTRODUCTION

The Air Force Center for Environmental Excellence is conducting a nationwide application of an innovative technology for free-product recovery and soil bioremediation. The technology tested in the Bioslurper Initiative is vacuum-enhanced free-product recovery/bioremediation (bioslurping). The field test and evaluation are intended to demonstrate the initial feasibility of bioslurping by measuring system performance in the field. System performance parameters, mainly free-product recovery, will be determined at numerous sites. Field testing will be performed at many sites to determine the effects of different organic contaminant types and concentrations and different geological conditions on bioslurping effectiveness.

Plans for the field test activities are presented in two documents. The first is the overall test plan and technical protocol for the entire program, titled *Test Plan and Technical Protocol for Bioslurping* (Battelle, 1995). The overall plan is supplemented by plans specific to each test site. The concise site-specific plans effectively communicate regulatory background to base personnel.

The overall test plan and protocol was developed as a generic plan for the Bioslurper Initiative to improve the accuracy and efficiency of test plan preparation. The field program requires installation and operation of the bioslurping system supported by a wide variety of site characterization, performance monitoring, and chemical analysis activities. The basic methods to be applied from site to site do not change. Preparation and review of the overall plan allows efficient documentation and review of the basic approach to the test program. Peer and regulatory review were performed for the overall plan to ensure the credibility of the overall program.

This letter report is the site-specific plan for application of bioslurping at Havre Air Force Station, Montana. It was prepared based on site-specific information received by Battelle from Havre AFS and other pertinent site-specific information to support the generic test plan.

Site-specific information for Havre AFS included data for three potential test locations. Each location is within the same base residential area. Several housing units in this area were subject to Underground Storage Tank (UST) leakage of heating oil. An initial review of the data indicates that Well MW-F is the most likely candidate for the bioslurper pilot test. If MW-F is found unsuitable for testing, Well MW-7 or MW-G may be viable alternatives.

2.0 SITE DESCRIPTION

The information presented in this section was summarized from the document titled "IRP Preliminary Remedial Design at Havre AFS" prepared byMatney-Frantz Engineering, P.C. (December 1994). A diagram of the remedial investigation area is shown as Figure 1. Monitoring wells MW-7 and MW-F are located within the proposed testing area and have shown measurable free product thickness. Figure 2 is a schematic diagram of the housing facilities and monitoring wells located in the remedial investigation area. Monitoring well construction diagrams are provided in Appendix A.

Site history indicates that many underground storage tanks were installed around the site in the 1950's. The USTs were used to store heating oil and diesel fuel. In 1984, the Investigative Restoration Program was employed at Havre AFS to determine releases of heating oil and diesel fuel that may pose a threat to human health and the environment in the area. It was found that 19 out of 26 USTs in the Havre housing area had leaked fuel oil into the surrounding soils. The USTs were removed in September 1992.

2.1 Site Geology

Havre AFS geologic conditions are characterized by approximately 15 feet of soil and unconsoildated material which is underlain by the Upper Cretaceous Bearpaw Shale. The unconsolidated materials are mostly comprised of fine sandy loam and clay loam. These loams are generally derived from parent materials of glacial till and tend to form deep soil horizons.

2.2 Aquifer Characteristics

At Havre AFS depth to groundwater varies from 10 to 17 feet below ground surface. Groundwater generally occurs in sand lenses lying atop the sandy and clay loams. Measurements in wells at the housing facility at Havre AFS indicated a hydraulic conductivity of 0.69 ft/day. Subsequent measurements gave a hydraulic conductivity of 0.0071 to 0.31 ft/day.

2.3 Site Contamination

Data indicates that the well that is most likely to yield significant amounts of free product is MW-F. Well #MW-F had the largest fuel thickness during the June 27, 1994, measurement (2.21'of free floating product) and has shown the greatest amount of free-product recovery throughout the measurement period (data presented in Appendix A). The type of free product in this well is heating oil. Soil samples collected during the UST removal indicated levels of TPH (as diesel) to be 35,200 mg/kg at a depth of 1 foot in the well #MW-F vicinity. A table which contains TPH concentrations in soil from soil collected during the UST removal is presented in Appendix A. Figure 2 is a site map which displays the arrangement of monitoring wells in the area of interest. Well MW-7, which may serve as an alternative well for the bioslurper pilot test, had a fuel thickness value of 0.32' during the June measurement. MW-G was installed as a free product recovery well after free product was discovered in the soil boring. No specific data has been generated for this well. Site characterization will begin with Well MW-F. If preliminary site characterization indicates that this well is unsuitable, or if site logistics prevent the use this well, Well MW-7 and Well MW-G will be evalutated as the potential bioslurper test site.

3.0 PROJECT ACTIVITIES

The following field activities are planned for the bioslurper pilot test at Havre AFS. Additional details about the activities are presented in the *Test Plan and Technical Protocol for Bioslurping* (Battelle, 1995). As appropriate, specific sections in the generic Bioslurping Protocol assessment are referenced. Table 1 shows the schedule of activities for the Bioslurper Initiative at Havre AFS.

3.1 Mobilization to the Site

After the site-specific test plan is approved, Battelle staff will mobilize equipment. The 20' by 10' flatbed trailer will be shipped in advance of staff arrival. In case any other equipment used during the pilot test is sent in advance of Battelle staff arrival, the Base Point of Contact (POC) will be asked to find a suitable holding facility to receive the bioslurper pilot test equipment so that it will be easily accessible to the Battelle staff when they arrive with the remainder of the equipment. The exact mobilization date will be confirmed with the Base POC as far in advance of fieldwork as is possible. The Battelle POC will provide the Air Force POC with information on each Battelle employee who will be on site. Battelle personnel will be mobilized to the site after it has been confirmed that the shipped equipment has been received by Havre AFS.

Table 1. Schedule of Bioslurper Test Activities

Pilot Test Activity	Schedule
Mobilization	Day 1-2
Site Characterization	Day 2-3
Baildown Tests and Product/Groundwater Interface Monitoring	
Soil-Gas Survey (limited)	
Slug Tests	
Monitoring Point Installation (3 MPs)	
Soil Sampling (TPH, BTEX[1], physical characteristics)	
System Installation	Day 2-3
Test Startup	Day 3
Skimmer Test (2 days)	Day 3-4
Bioslurper Vacuum Extraction (4 days)	Day 6-9
Soil-Gas Permeability Testing	Day 6
Skimmer Test (continued) (1 day)	Day 10
In Situ Respiration Test — air/helium injection	Day 10
In Situ Respiration Test — monitoring	Day 11-16
Drawdown Pump Test (2 days)	Day 11-12
Demobilization/Mobilization	Day 13-14

[1] BTEX = benzene, toluene, ethylbenzene, and total xylenes

3.2 Site Characterization Tests

3.2.1 Baildown Tests

The baildown test is the primary test for selection of the bioslurper test well. Baildown tests will be performed at wells that contain measurable thicknesses of light, nonaqueous-phase liquid (LNAPL) to estimate the LNAPL recovery potential at those particular wells. Monitoring wells MW-7 and MW-F at the Havre Housing Facility will be tested because they have shown measurable free product thickness in recent surveys. The well exhibiting the highest rate of LNAPL recovery during the baildown tests will be selected for the bioslurper extraction well. Table 2 presents the volume of fuel

that would be present in a 1-ft cross section of various well diameters. Detailed procedures for the baildown tests are provided in Section 5.6 of the generic Bioslurping Protocol.

Table 2. Free Recovery Volumes per Unit Length for Common Well Casing Diameters

Nominal Pipe Size	Schedule 40 Pipe (gallons/ft)	Schedule 80 Pipe (gallons/ft)
2.0	0.174	0.153
3.0	0.384	0.343
4.0	0.661	0.597
6.0	1.50	1.35

3.2.2 Soil-Gas Survey (Limited)

A small-scale soil-gas survey will be conducted to identify the best location for installation of the bioslurping system. The soil-gas survey will be conducted in areas where historical site data indicate the highest contamination levels, namely the areas around MW-F and MW-7. These areas will be surveyed to select the locations for installation of soil-gas monitoring points. Soil-gas monitoring points will be located in areas that exhibit the following characteristics.

1. Relatively high TPH concentrations (10,000 ppm or greater).

2. Relatively low oxygen concentrations (between 0% and 2%).

3. Relatively high carbon dioxide concentrations (depending on soil type, between 2% and 10% or greater).

To obtain further information about the soil-gas survey, consult Section 5.2 of the generic Bioslurping Protocol.

3.2.3 Monitoring Point Installation

Upon conclusion of the initial soil-gas survey and baildown tests, at least three soil-gas monitoring points will be installed. Monitoring points will be used to determine the radius of influence in the vadose zone of the free-product recovery system. In addition, the monitoring points will be located in highly contaminated soils within the free-phase plume and will be positioned to allow detailed monitoring of the in situ changes in soil-gas composition caused by the bioslurper system. The components of soil-gas monitoring points are shown in Figure 3. A general arrangement for soil-gas monitoring points at MW-F in the Housing Area is presented in Figure 4. A shematic diagram of MW-F, and MW-G is presented in Appendix B. Information on monitoring point installation can be found in Section 4.2.1 of the generic Bioslurping Protocol.

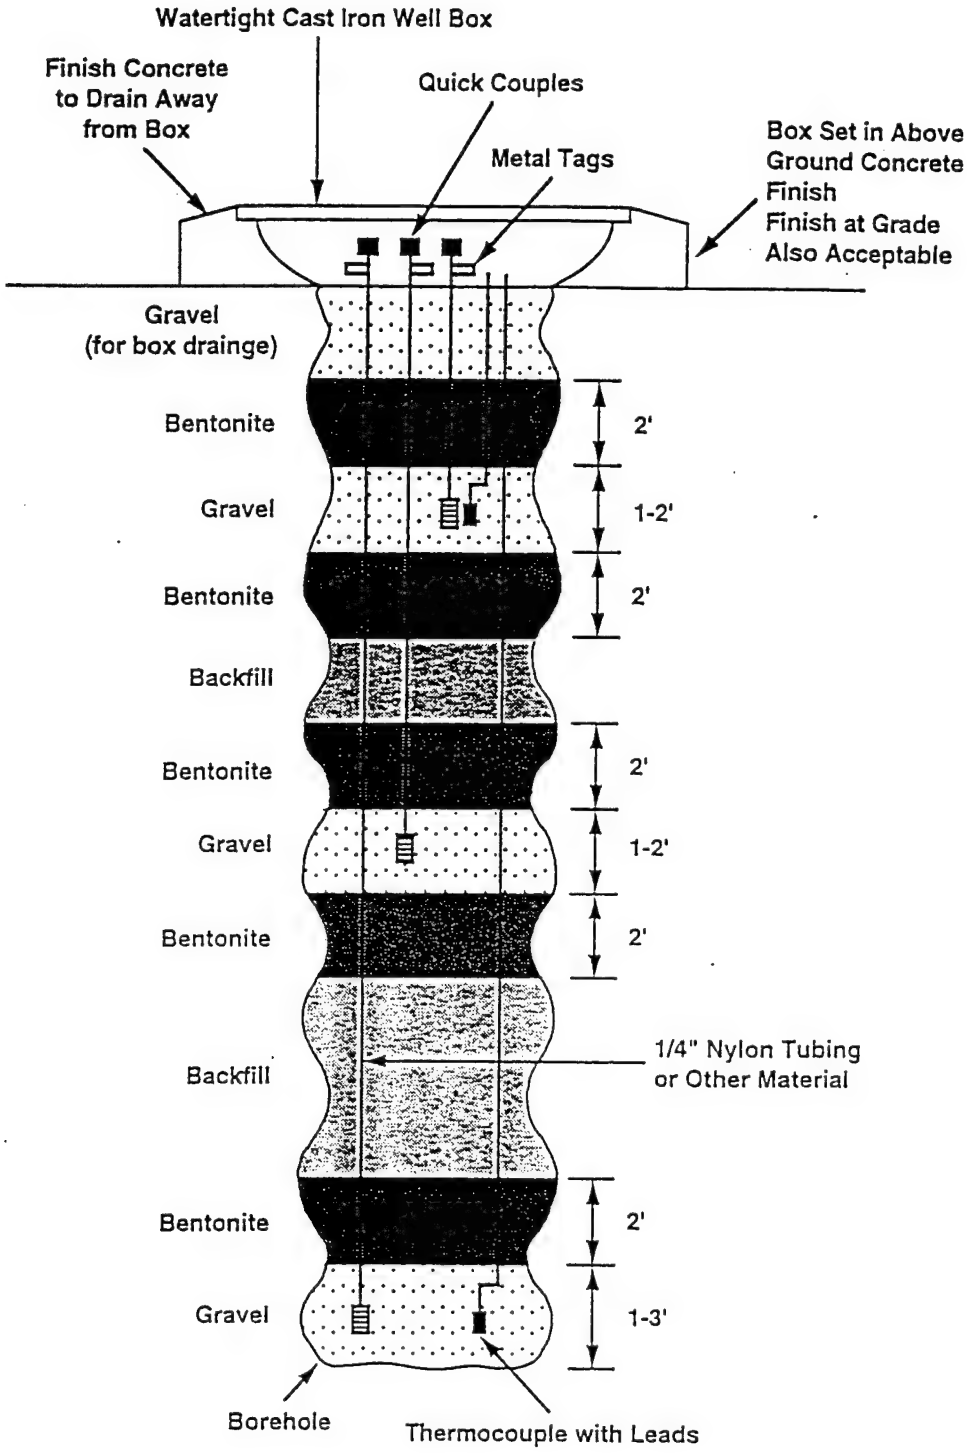

Figure 3. Schematic Diagram of a Typical Soil-Gas Monitoring Point

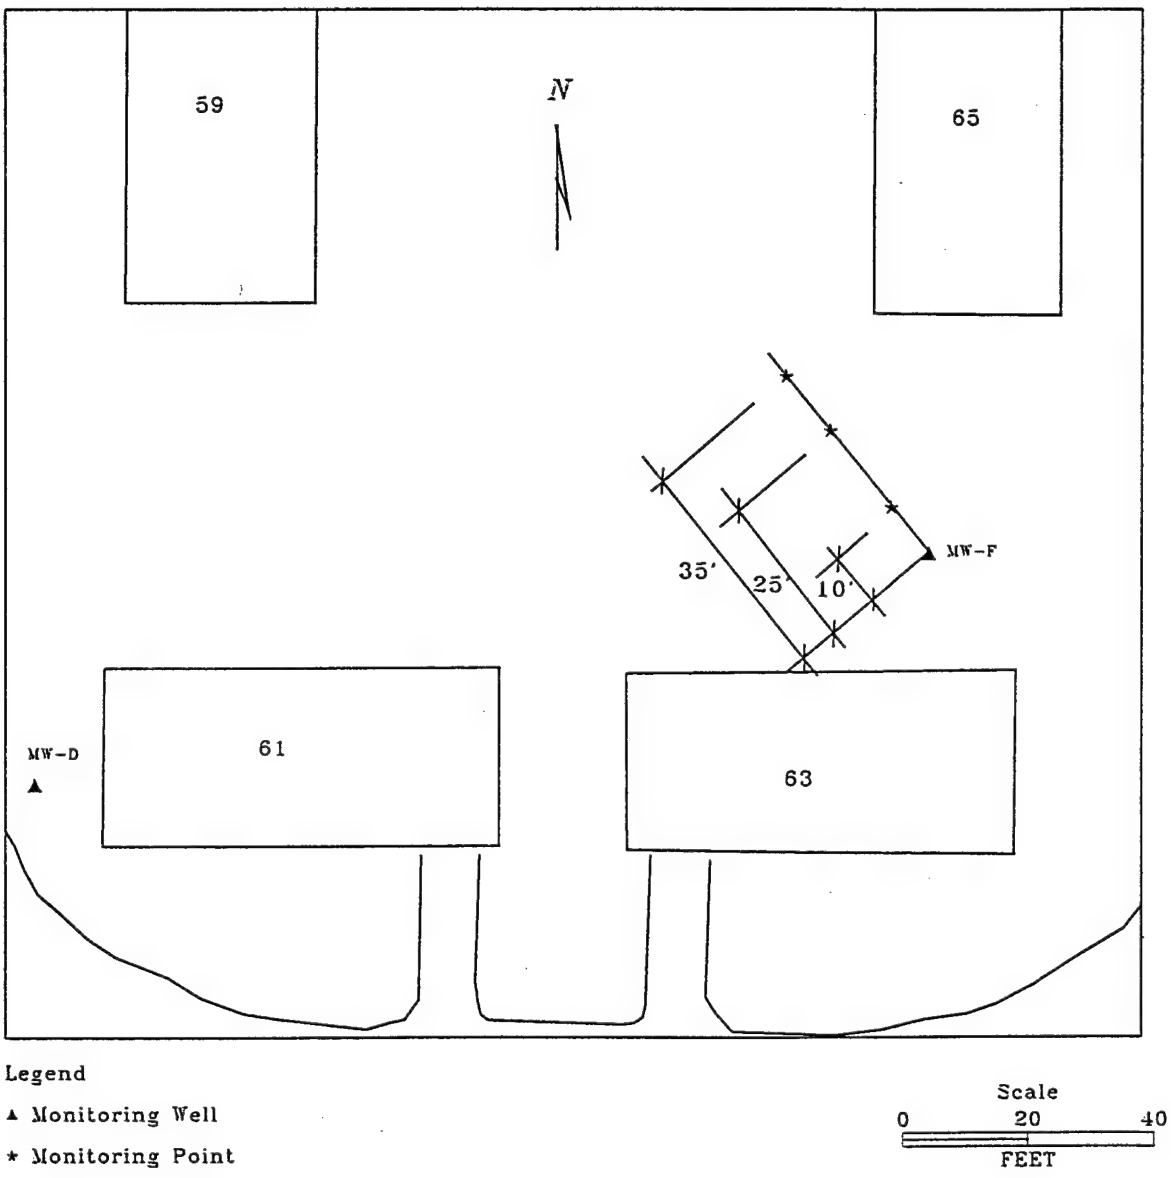

Figure 4. Conceptual Arrangement for Soil-Gas Monitoring Points at MW-F in the Housing Area

3.2.5 Soil Sampling

Soil samples will be collected to determine the physical and chemical composition of the soil near the bioslurper test site. Soil samples will be collected from the boreholes advanced for monitoring point installation at two or three locations at the site chosen for the bioslurper test. Generally, samples will be collected from the capillary fringe over the free product.

Soil samples will be analyzed for particle-size distribution, bulk density, porosity, moisture content, benzene, toluene, ethylbenzene, and xylenes (BTEX), and TPH. Section 5.5.1 of the generic Bioslurping Protocol will be consulted for information on the field measurements and sample collection procedures for soil sampling.

3.3 Bioslurper System Installation and Operation

Once the well to be used for the pilot tests has been identified, the bioslurper pump and support equipment will be installed and the pilot tests will be initiated.

3.3.1 System Setup

Figure 5 shows a flow diagram of the bioslurper process. Figure 6 is a schematic diagram of a typical bioslurper well and slurper tube that will be installed on an existing groundwater well (i.e., monitoring wells MW-F or MW-7). Before the LNAPL recovery tests are initiated, all relevant baseline field data will be collected and recorded. These data will include soil-gas concentrations, initial soil-gas pressures, depth to groundwater, and LNAPL thickness. Ambient soil and all atmospheric conditions (e.g., temperature, humidity, barometric pressure) also will be recorded. All emergency equipment (i.e., emergency shutoff switches and fire extinguishers) will be installed and checked for proper operation at this time.

A clear, level 20- by 10-ft area near the well selected for the bioslurper test installation will be identified to station the equipment required for bioslurper system operation. For more information on bioslurper system installation, consult Section 6.0 of the generic Test Plan and Technical Protocol.

3.3.2 System Shakedown

A brief startup test will be conducted to ensure that the system is constructed properly and operates safely. All system components will be checked for problems and/or malfunctions. A checklist will be provided to document the system shakedown.

3.3.3 System Startup and Test Operations

After installation is complete and the bioslurper system is confirmed to be operating properly, the LNAPL recovery tests will be started. The Bioslurper Initiative has been designed to evaluate the effectiveness of bioslurping as an LNAPL recovery technology relative to conventional gravity-driven LNAPL recovery technologies. The Bioslurper Initiative Test Plan and Technical Protocol includes three separate LNAPL recovery tests: (1) a skimmer pump test, (2) a bioslurper pump test, and (3) a drawdown pump test. The three recovery tests are described in detail in Section 7.3 of the generic Test Plan and Technical Protocol.

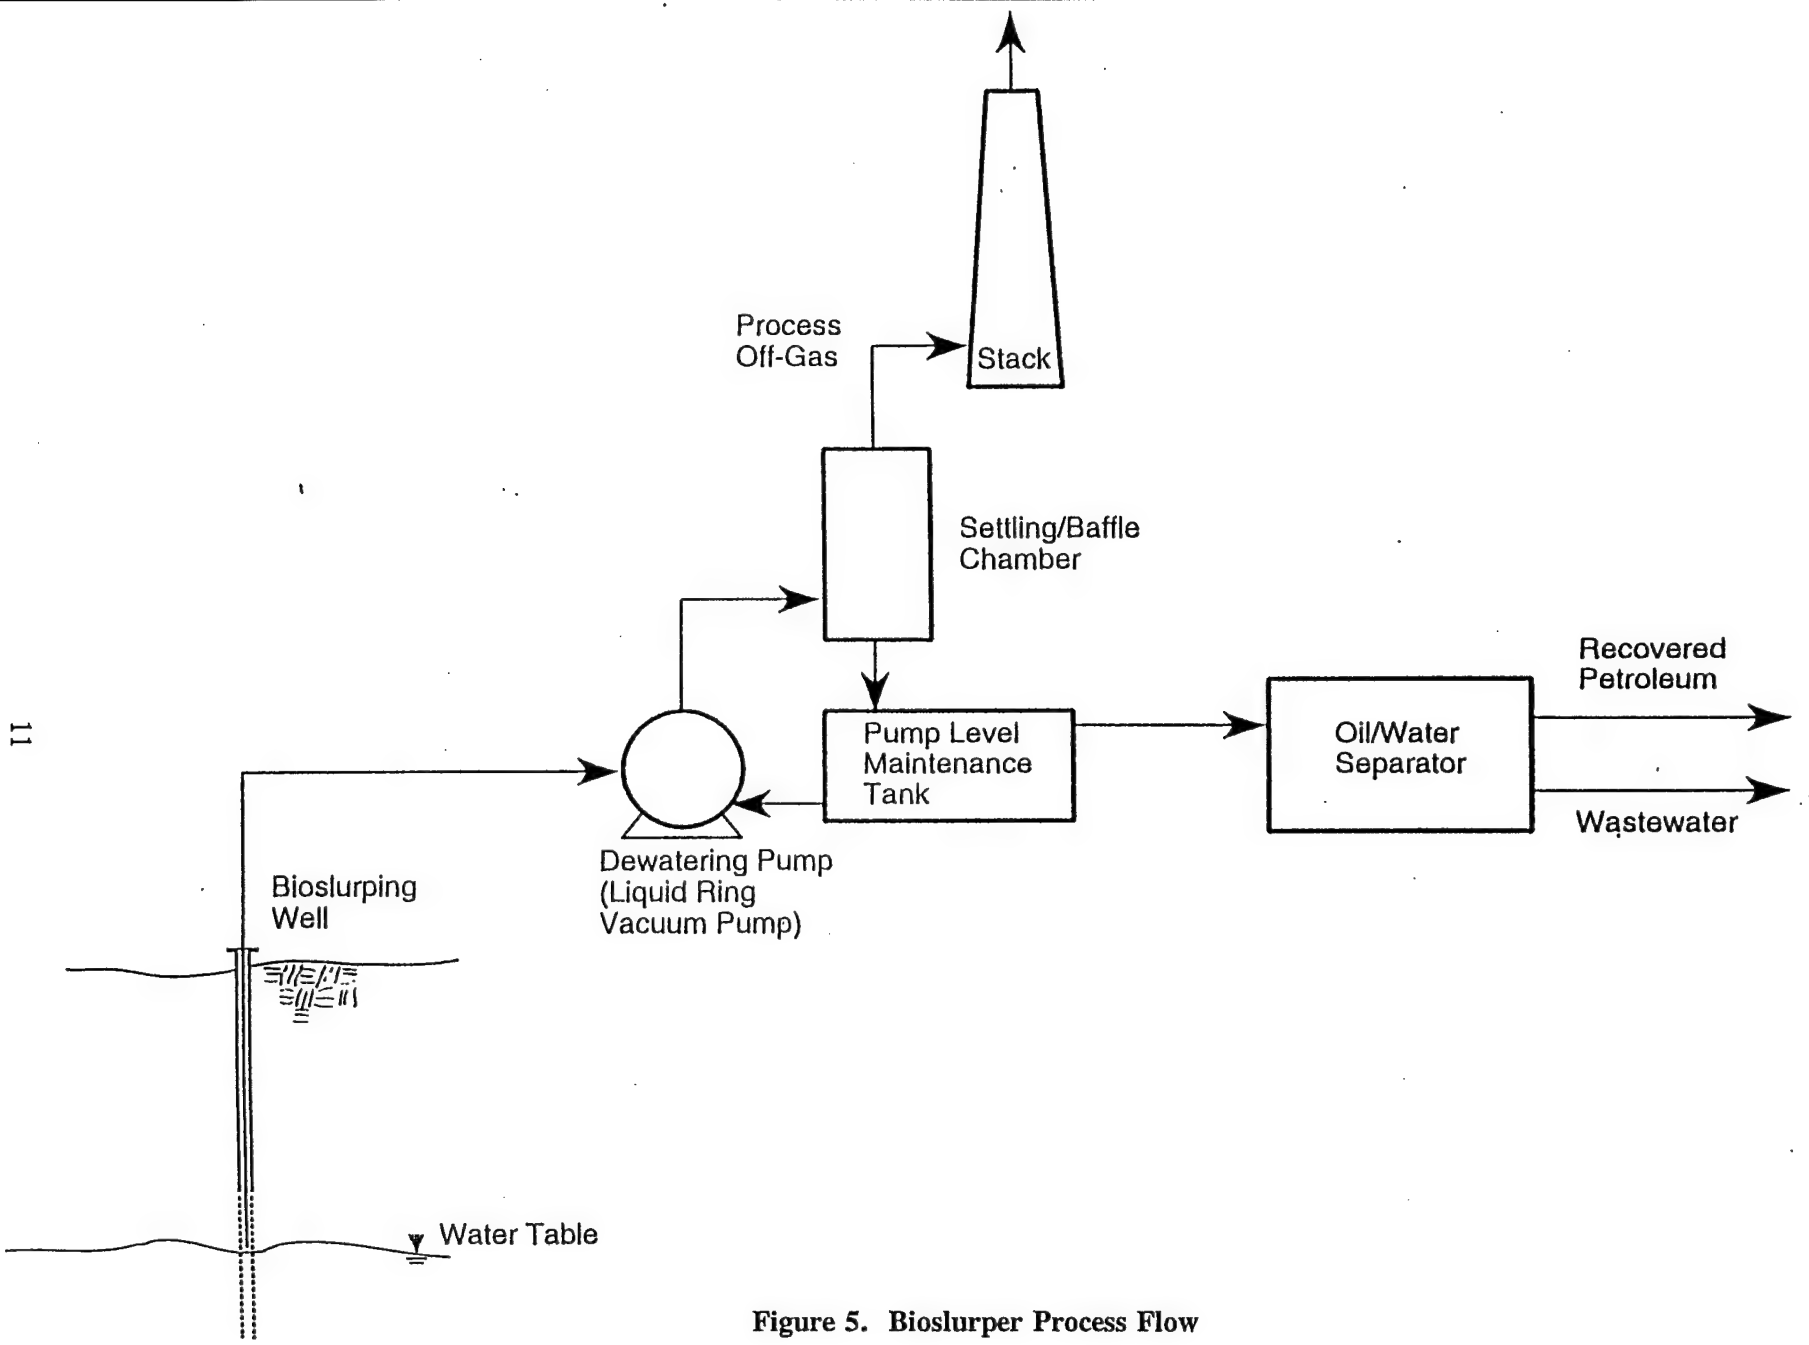

Figure 5. Bioslurper Process Flow

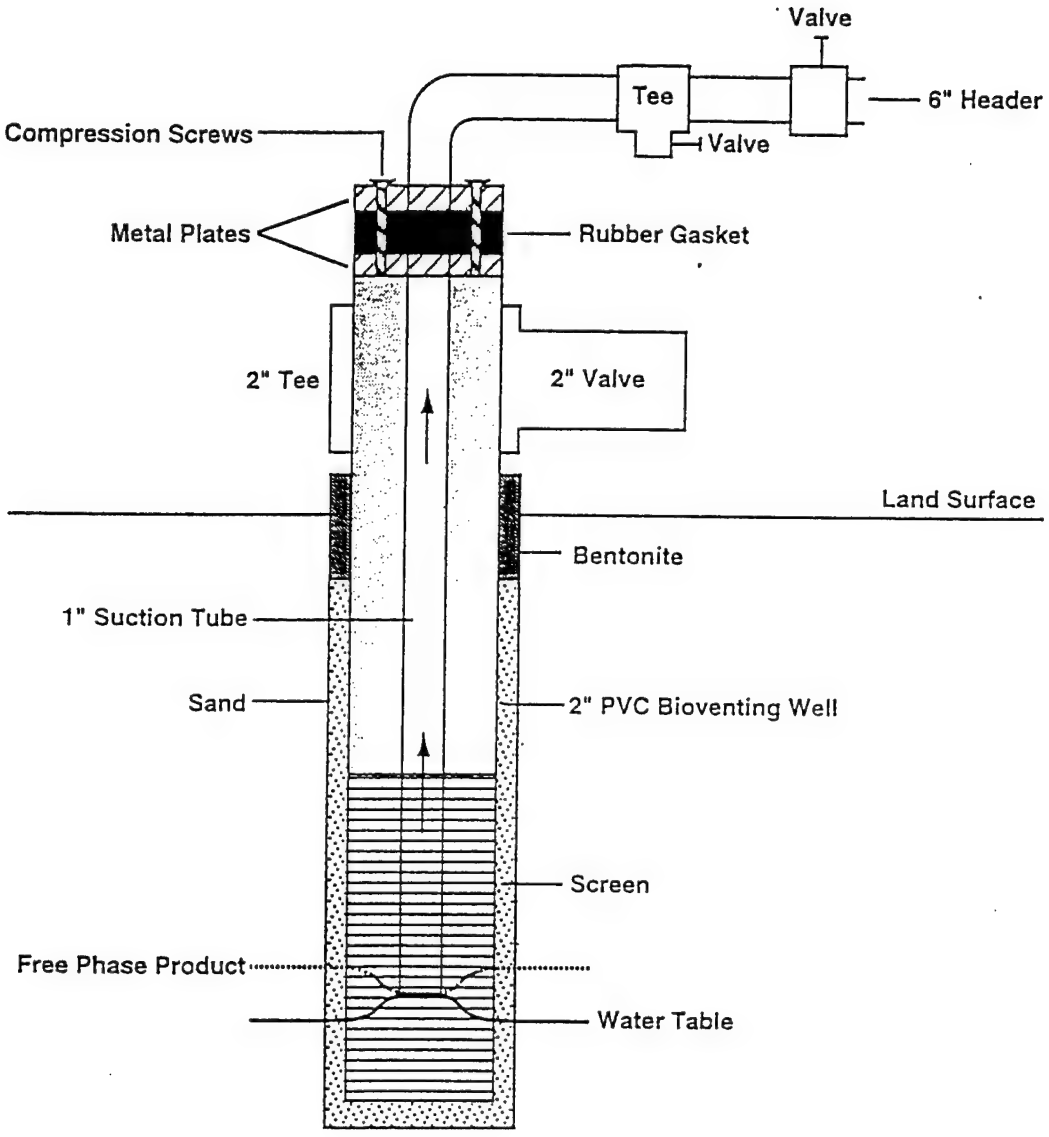

Figure 6. Schematic Digram of a Typical Bioslurper Well

The bioslurper system operating parameters that will be measured during operation are vapor discharge, aqueous effluent, LNAPL recovery volume rates, vapor discharge volume rates, and groundwater discharge volume rates. Vapor monitoring will consist of periodic monitoring of TPH using hand-held instruments supplemented by two samples collected for detailed laboratory analysis. A total of two samples of aqueous effluent will be collected for analysis of BTEX and TPH. Recovered LNAPL volume will recorded using an in-line flow-totalizing meter. The off-gas discharge volume will be measured using a calibrated pilot tube, and the groundwater discharge volume will be recorded using an in-line flow-totalizing meter. Section 8.0 of the generic Test Plan and Technical Protocol describes process monitoring of the bioslurper system.

3.3.4 Soil-Gas Permeability Test

A soil-gas permeability test will be conducted concurrently with startup of the bioslurper pump test. Soil-gas permeability data will support the process of estimating the vadose zone radius of influence of the bioslurper system. Soil-gas permeability results also will aid in determining the number of wells required if it is decided to treat the site with a large-scale bioslurper system. The soil-gas permeability test method is described in Section 5.7 of the generic Test Plan and Technical Protocol.

3.3.5 LNAPL and Water-Level Monitoring

During the bioslurper pump test, the LNAPL and groundwater levels will be monitored in a well adjacent to the extraction well. The top of the monitoring well will be sealed from the atmosphere so the subsurface vacuum will be contained. Additional information for the monitoring of fluid levels during the bioslurper pilot test is located in Section 4.3.4 of the generic Test Plan and Technical Protocol.

3.3.6 In Situ Respiration Test

An in situ respiration test will be conducted after completion of the LNAPL recovery tests. The in situ respiration test will involve injection of air and helium into selected soil-gas monitoring points, followed by monitoring changes in concentration of oxygen, carbon dioxide, TPH, and helium in soil gas. Measurement of the soil-gas composition typically will be conducted at 2, 4, 6, and 8 hours and then every 4 to 12 hours for about 2 days. Timing of the tests will be adjusted based on oxygen-use rate. If oxygen depletion occurs rapidly, more frequent monitoring will be conducted. If oxygen depletion is slow, less frequent readings will be acceptable. The oxygen utilization rate will be used to estimate the biodegradation rate at the site. Further information on the procedures and data collection for in situ respiration testing is given in Section 5.8 of the generic Bioslurping Protocol.

3.3.7 Extended Testing

The AFCEE/ERT has the option of extending the operation of the bioslurper system for up to 6 months if LNAPL recovery rates are promising and viable long-term vapor and aqueous discharge requirements have been identified. If extended testing is to be performed, Havre AFS will need to provide electrical power for long-term operation of the bioslurper pump. Disposition of all generated wastes and routine operation and maintenance of the system will be the Air Force's responsibility. Battelle will provide technical support during the extended testing operation.

3.4 Demobilization

Once all necessary tests have been completed at Havre AFS, the equipment will be disassembled and moved back to the holding facility by Battelle staff; it will remain there until its next destination is determined. Battelle staff will receive this information and will be responsible for shipping of the equipment to the next site before leaving Havre AFS.

4.0 BIOSLURPER SYSTEM DISCHARGE

4.1 Vapor Discharge Disposition

Battelle expects that the operation of the bioslurper test system at the Havre AFS site will not require a waiver or a point source air release registration. Based on a review of data from Havre AFS Housing Area, it is estimated that the mass of TPH released to the atmosphere at Havre AFS will be less than 5 lb TPH/day. The discharge of benzene is estimated to be less than 1 lb/day. These values are based on average discharge levels at two bioslurper test sites (Andrews AFB and Bolling AFB - Site #1) contaminated with the same type of heating oil as that found at Sites 3 and 4. These values may vary depending on soil gas concentrations and soil gas permeability.

The data for TPH and benzene discharge levels at four previous bioslurper sites are presented in Table 3. The relatively high TPH discharge level at Travis AFB is partially due to the extraction rate of the vapors. This estimated extraction rate is the maximum rate a 3-hp pump will achieve and should be much lower at Havre AFS. The vapor stream generated by the bioslurper system can be discharged directly to the atmosphere because of the short duration of the test and the low concentration levels of TPH and benzene in the stream.

To ensure the safety and regulatory compliance of the bioslurper system, vapor discharge samples (TPH, O_2, and CO_2) will be collected periodically throughout the bioslurper pilot test, and field soil-gas screening instruments will be used to monitor vapor discharge concentration. The volume of vapor discharge will be monitored daily using airflow instruments. If state regulatory requirements will not permit the expected amount of organic vapor discharge to the atmosphere, the Base POC should inform AFCEE and Battelle so that alternative plans can be made prior to mobilization to the site. Table 4 presents information typically required to complete an air release registration form.

Table 3. Benzene and TPH Discharge Levels at Previous Bioslurper Test Sites

Site Location	Fuel Type	Extraction Rate (scfm)	Benzene (ppmv)	TPH (ppmv)	Benzene Discharge (lb/day)	TPH Discharge (lb/day)
Wright-Patterson AFB	JP-4 Jet Fuel	3	ND	595	0.0	1.0
Bolling AFB (Site #1)	No. 2 Fuel Oil	4	0.2	153	0.0003	0.009
Bolling AFB (Site #2)	Gasoline	21	370	70,000	2.3	470.1
Andrews	No. 2 Fuel Oil	8	16	2,000	0.001	0.2
Travis AFB	JP-4 Jet Fuel	20	100	10,800	0.58	126.4

ND = not detected.

Table 4. Air Release Summary Information

Data Item	Air Release Information
Contractor Point of Contact	Jeff Kittel, (614) 424-6122
Contractor address	Battelle, 505 King Avenue, Columbus, OH 43201
Estimated total quantity of petroleum product to be recovered	TBD
Description of petroleum product to be recovered	No. 2 Fuel Oil
Planned date of test start	TBD
Test duration	9 days (active pumping)
Maximum total quantity of VOC release	~5.0 lb/day (4 lb TPH, <1.0 lb benzene)
Stack height above ground level	10 ft

4.2 Aqueous Influent/Effluent Disposition

The flowrate of groundwater pumped by the bioslurper will be less than 5 gpm. However, it may be necessary to obtain a groundwater pumping waiver or registration permit in Illinois. If one is required, the base POC will inform Battelle of the necessary steps in obtaining the waiver or permit. Operation of the bioslurper system will generate an aqueous waste discharge that will be passed through an oil/water separator. The intention of Battelle staff will be to dispose of the wastewater by discharging it directly to the Base sanitary sewer system. If existing Base wastewater channels can be used, no water discharge permits will be required.

4.3 Free-Product Recovery Disposition

The bioslurper system will recover free-phase product from the pilot tests performed at Havre AFS. Free product recovered by the bioslurping tests will be turned over to the Base for disposal and/or recycling. The volume of free product recovered from the Base will not be known until the tests have been performed. The maximum recovery rate for this system is 5 gpm, but the actual rate of LNAPL recovery likely will be much lower.

5.0 SCHEDULE

The schedule for the bioslurper fieldwork at Havre AFS will depend on approval of the project Test Plans. Battelle will determine a definitive schedule as soon as possible after approval is received. Battelle will have two to three staff members on site for approximately 2 weeks to conduct all necessary pilot testing. At the conclusion of the field testing at Havre AFS, all staff will return their Base passes and remove all bioslurper field testing equipment from the Base before leaving the site.

6.0 PROJECT SUPPORT ROLES

This section outlines some of the major functions of personnel from Battelle, Havre AFS, and AFCEE during the bioslurper field test.

6.1 Battelle Activities

Battelle's responsibility in the Bioslurper Initiative at Havre AFS will be to supply the staff and equipment necessary to perform all the tests on the bioslurper system. Battelle also will provide technical support in the areas of water and vapor discharge permitting, digging permits, staff support during the extended testing period, and any other technical areas that need to be addressed.

6.2 Havre AFS Support Activities

To support the necessary field tests at Havre AFS, the Base must be able to provide the following:

1. Any digging permits and utility clearances that need to be obtained prior to the initiation of the fieldwork. Any underground utilities should be clearly marked to reduce the chance of utility damage and/or personal injury during soil-gas probe and possible well installation. Battelle will not begin field operations without these clearances and permits.

2. The Air Force will be responsible for obtaining Base and site clearance for the Battelle staff that will be working at the Base. The Base POC will be furnished with all necessary information on each staff member at least 1 week prior to field startup.

3. Access to the local sanitary sewer must be furnished so that Battelle staff can discharge the bioslurper aqueous effluent directly to the Base treatment facility.

4. Regulatory approval, if required, must be obtained by the Base POC prior to startup of the bioslurper pilot test. As stated previously, it is likely that a waiver to allow air releases or a point source air release registration will be required for emissions of approximately <5.0 lb/day of TPH and <1.0 lb/day of benzene. It may be necessary to obtain a waiver for pumping and discharging groundwater at a rate of 5 gpm. The Base POC will obtain all necessary Base permits prior to mobilization to the site. Battelle will provide technical assistance in preparing regulatory approval documents.

5. The Base also will be responsible for the disposition of all waste generated from the pilot testing. Such waste includes any soil cuttings generated from drilling, and all aqueous wastestreams produced from the bioslurper tests. All free product recovered from the bioslurper operation will be disposed of or recycled by the Base. Battelle will provide technical assistance in disposing of the waste generated from the bioslurper pilot test.

6. Before field activities begin, the Health and Safety Plan will be finalized with information provided by the Base POC. Table 5 is a checklist for the information required to complete the Health and Safety Plan. All emergency information will be obtained by the Site Health and Safety Office before operations begin.

6.3 AFCEE Activities

The AFCEE POC will act as a liaison between Battelle and Base staff. The AFCEE POC will ensure that all necessary permits are obtained and the space required to house the bioslurper field equipment is found. The following is a listing of Battelle, AFCEE, and Havre AFS staff who can be contacted in cases of emergency and/or for required technical support during the bioslurper field initiative tests at Havre AFS.

Battelle POCs	Jeff Kittel	(614) 424-6122

Attn: Al Pollack

Sampled: 10/10/95 Received: 10/17/95 Analyzed: 10/20/95

Matrix: [X] Soil [ ] Water [ ] Waste

Analysis Requested: TPH - Total Petroleum Hydrocarbons-Extractable Quantitated As Diesel
BTXE - Benzene,Toluene,Xylenes,Ethylbenzene

Methodology: TPH - Modified 8015/DHS LUFT Manual/BLS-191
BTXE - EPA Method 624/8240

TPH/BTXE Results:

Client ID/ Lab ID	Parameter	Concentration	Detection Limit	
HAV-MPA-10.0'-10.5' /BMI101795-04	TPH *	6,700	100	mg/Kg
	Benzene	ND	500	ug/Kg
	Toluene	ND	500	ug/Kg
	Total Xylenes	1,100	500	ug/Kg
	Ethylbenzene	1,300	500	ug/Kg
HAV-MPD-10.0'-10.5' /BMI101795-06	TPH *	13,000	100	mg/Kg
	Benzene	ND	1,000	ug/Kg
	Toluene	1,200	1,000	ug/Kg
	Total Xylenes	32,000	1,000	ug/Kg
	Ethylbenzene	1,600	1,000	ug/Kg

* - Components are in the range of diesel.

APPENDIX D

DATA SHEETS FROM THE SHORT-TERM PILOT TEST

Baildown Test Record Sheet

Site: Havre AFS

Well Identification: MW-F

Well Diameter (OD/ID): 4"

Date at Start of Test: 10/10/95 Sampler's Initials: MP, AP

Time at Start of Test: 1041

Initial Readings

Depth to Groundwater (ft)	Depth to LNAPL (ft)	LNAPL Thickness (ft)	Total Volume Bailed (L)
15.05	13.55	1.5	9.5 L

Test Data

Sample Collection Time	Depth to Groundwater (ft)	Depth to LNAPL (ft)	LNAPL Thickness (ft)
10/10/95-1041	14.79	14.70	0.09
1047	14.72	14.62	0.10
1054	14.61	14.56	0.05
1109	14.47	14.36	0.11
1143	14.26	14.12	0.14
1254	14.08	13.92	0.16
1332	14.02	13.88	0.14
1443	13.99	13.83	0.16
1547	13.96	13.78	0.18
1702	13.96	13.76	0.20
10/11/95-0840	14.04	13.79	0.25
-1803	13.98	13.76	0.22
